Keywords

place-based research, transferability, land use, tele-coupling, scenario analysis.

Text

1. Introduction

30 Human land-use activities have transformed most of the Earth's land surface (Foley *et al*
31 2005, Ellis 2011, Gauthier *et al* 2015). While land-use activities differ in many ways
32 across the world, their combined impact is becoming a force of global importance.
33 Consequently, sustainable land management (SLM) has been identified as a key lever for
34 achieving global sustainability. For example, six out of 17 sustainable development goals
35 (SDGs), adopted in the United Nations 2030 Agenda for Sustainable Development, relate
36 directly to land management: (i) land management is key for providing goods and
37 services for human kind relating to "zero hunger" (SDG 2); (ii) land management is
38 responsible for 20-40% of GHG emissions relating to "climate action" (SDG 13), and (iii)
39 land management is a major driver of biodiversity loss relating to "life of land" (SDG 15).
40 Indirectly land management affects "affordable clean energy" (SDG 7) and "sustainable
41 cities and communities" (SDG 11).

42 A growing human population, associated with increasing consumption rates and
43 demands on commodities, requires a true paradigm shift regarding the management of
44 the land for long-term sustainability. At the same time we are witnessing a progressive
45 scarcity of available productive land, and the production peak of many renewable
46 resources has already been passed (Lambin and Meyfroidt 2011, Seppelt *et al* 2014).
47 These demands and the limits to supply underlie the many linkages between the
48 different social, economic and ecological goals and targets that are being charted out by
49 Agenda 2030 (Geijzendorffer *et al* 2017). Pathways to some goals are synergistic, while
50 others present trade-offs for their mutual achievement. For example, an increase of
51 provisioning goods and services from ecosystems, such as food and fibre, could be
52 achieved through further intensification of land use (Mauser *et al* 2015), which might
53 lead to an increasing loss of biodiversity (Newbold *et al* 2015, Gerstner *et al* 2014, Stein
54 *et al* 2014) but also results in higher greenhouse gas (GHG) emission through higher
55 energy use and fertilizer application. At the same time, biodiversity has to be maintained
56 for many societal objectives including its potential to support ecosystem functions such
57 as pollination (Cardinale *et al* 2012, Seppelt *et al* 2016). A significant reduction of GHG
58 emissions through large-scale deployment of new biofuels is in conflict with the
59 production of food or conservation of natural habitats for biodiversity or carbon
60

1
2 60 storage. The specific nature of the conflicts and synergies between these different
3
4 objectives strongly depends on the local land system and the environmental, socio-
5
6 economic and cultural context in which this land system is operating. Thus, achieving
7
8 one SDG might compromise others (Pradhan *et al* 2017) and trade-offs on various scales
9
10 need to be expected, which can be moderated by appropriate land management.

11
12 65 Whilst place-based research provides essential knowledge on the biophysical and socio-
13
14 economic boundaries of land use, its findings are naturally contingent upon the specific
15
16 geographical context and rarely account for off-site effects. The conversion of a
17
18 conventional agricultural system at one location to organic farming may have positive
19
20 impacts on local sustainability, but it may, due to lower production, displace some
21
22 70 impacts to other locations that need to compensate for the loss of production. On the
23
24 other hand, many land use drivers such as climate change, population growth or
25
26 consumption patterns are well captured at the global scale, but there are significant
27
28 uncertainties about how they interact with local conditions. Both regional and global
29
30 75 socio-economic and biophysical processes. These uncertainties and incongruences in
31
32 spatial scales prevent effective integration, synthesis and transferability of findings from
33
34 research to sustainable land management.

35
36 Against this background, we here review and synthesize the contributions of the focus
37
38 collection on “Cross-scale Feedbacks in Global Sustainable Land Management”, which
39
40 80 collates papers that investigate the links between global change processes and local
41
42 realities through, e.g. integration of local and global drivers impacting economic and
43
44 biophysical processes or assessing the transferability or up-scaling of findings from
45
46 place-based research.

47 48 **2. Synthesis: Emerging Topics in Sustainable Land Management and Land** 49 50 **Systems Research** 51 52 85

53
54 The articles in this focus issue illustrate new approaches to investigate global and
55
56 regional land systems, and identify key research frontiers important for sustainable land
57
58 management across scales to achieve the SDGs. Three major clusters of research
59
60 90 frontiers have been identified: (1) new frameworks to understand cross-scale dynamics
of land-use systems, (2) synthesis of place-based research, and (3) addressing future
perspectives of land use by development of consistent scenarios.

2.1 New frameworks to understand cross-scale dynamics of land-use systems

Land management dynamics are seldom just local or place-specific anymore, but are influenced by multiple global drivers with complex connections to other places.

95 Improving our understanding of these different cross-scale dynamics, in diverse land-use systems is critical. Dorninger *et al* (2017) conceptualize the “human-nature connectedness” as a new methodological framework that can be applied in any region of the world to assess how closely connected people are to their regional ecosystems. The authors identify two key mechanisms that disconnect humans from nature on a regional scale: (1) the flow of external non-renewable inputs into the land-use system and (2) teleconnections with distant systems. While these mechanisms allow for greater regional resource use, they pose challenges for sustainability through waste generation, depletion of non-renewable resources and environmental burdens shifted to distant regions.

105 The topic of environmental burdens is elaborated by Pascual *et al* (2017), who argue for a better recognition of the distant, diffuse and delayed impacts that land management often has on biodiversity and ecosystem services. They define these impacts as “off-stage ecosystem service burdens” and identify four typical pathways based on biodiversity conservation policies, and the management of provisioning, regulating and cultural services. The authors advocate for their incorporation in land management decisions and ecosystem service assessments such as those conducted by the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES).

115 Finally, Sietz *et al* (2017) apply the emerging approach of “archetype analysis” and assess vulnerability in African drylands to environmental change. A cluster analysis reveals archetypical patterns of how vulnerable farming systems are to land degradation and support understanding the heterogeneity of vulnerability determinants (e.g. water availability, agro-ecological potential or population pressure) across sub-Saharan Africa. Importantly, their spatially explicit framework offers the opportunity of evaluating a specific region’s potentials and challenges in its wider context across nested scales.

2.2 Synthesis of Place-Based Research Results

While new conceptual and analytical frameworks such as the above provide guidance in designing specific analysis and provide suggestions for similarities between case

1
2 125 studies, a general methodology on the transferability of place-based research is
3
4 unresolved and defines the second emerging topic. Three studies focus on synthesis of
5
6 data and local case studies on sustainable land management, highlighting the need for
7
8 generalization and transferability of findings. Hermans-Neumann *et al* (2016) analyse
9
10 the drivers of changes in tropical forest products using a standardized, pan-tropical
11 130 dataset of more than 200 villages with forest access. Their analysis show that forest
12
13 resources (e.g. timber, fuel wood and food) declined over the last five years, though with
14
15 marked differences across continents. The strongest degradation of forest resources
16
17 occurred in places with both growing resource use and immigration.
18
19 Similarly, Carter *et al* (2017) synthesize comprehensive data on large scale land
20
21 135 acquisition (LSLA) to reveal that land available for agriculture, accessibility and political
22
23 stability are the main factors that explain whether a country will be targeted for LSLA.
24
25 The synthesis of such comprehensive datasets allows for globally comparative analyses
26
27 that go beyond case studies in terms of generalizable conclusions and transferability of
28
29 findings.
30
31 140 The issue of transferability is specifically addressed by Václavík *et al* (2016) who build
32
33 on a previously developed concept of land system archetypes (Václavík *et al* 2013,
34
35 Levers *et al* 2018) to investigate potential transferability of regional case studies that
36
37 focus on land management and ecosystem services across four continents. The proposed
38
39 145 method is offered as a blueprint for large research frameworks that need to assess the
40
41 relevance and representativeness of place-based research for other geographical areas
42
43 and to identify possible gaps in research efforts.

2.3 Future Perspectives and New Integrated Scenarios

44
45 Finally, the third emerging topic deals with potential future developments of land
46
47 management, based on scenarios which capture the diversity of land systems. Scenarios
48
49 150 of land management need to consider that land is a limited resource which can be used
50
51 to produce food and fibre or to maintain non-provisioning ecosystem services but that
52
53 trade-offs exist in the decisions how to manage land (Titeux *et al* 2017). Modelling
54
55 approaches that integrate the interplay of biophysical and socioeconomic factors in
56
57 scenarios of global or regional change are promising tools to study future land-use
58
59 155 impacts and trade-offs. Delzeit *et al* (2018) provide a set of scenarios of global drivers
60
61 until 2030 that can be used consistently in a range of regional and local case studies of
62
63 land use. The impacts of biofuel policies, dietary patterns, cropland expansion and

1
2 productivity changes on agricultural markets are investigated in a modelling framework
3 that couples an economic model with a crop growth model.
4
5

6
7 160 One of these global scenarios together with regionally-tailored land-use and climate
8 change scenarios is applied by Langerwisch *et al* (2018) who quantify the combined
9 effects of land-use and climate change on four ecosystem services in rice-production
10 regions in Southeast Asia. Here, the vegetation and hydrology model LPJmL shows clear
11 trade-offs in the future provision of ecosystem service, but also the potential of land
12 management to partially offset the negative impacts of climate change on rice
13 production, carbon storage and sequestration. Following a similar framework, Gutsch *et*
14 *al* (2018) quantify the effects of alternative land management scenarios and climate
15 165 impacts on forest variables indicating ecosystem services related to timber, habitat,
16 water and carbon. Again, the combination of modelling tools applied under scenarios of
17 future change allows to better balance the trade-offs between ecosystem services and
18 provides the base for future forest management optimization at the regional and
19 national scale.

31 **3. Outlook: Guiding questions of the emerging topics**

32
33 Obviously, a focus collection of publications as this cannot fully cover the complex topic
34 of sustainable land management in a comprehensive or exhaustive manner. Global land
35 175 management is characterized by a diverse set of key challenges. These range from
36 sustainable resource appropriation, the preservation of biodiversity and ecosystem
37 functioning, human well-being, equity and so forth, as comprehensively covered by the
38 SDGs, or as illustrated by Figure 1. Based on the emerging topics identified by and
39 discussed in the contributions of this focus collection we can collate key questions,
40 which serve for stimulation as well as for guidance of future research directions, c.f. Box

Figure 1: The diverse facets of global sustainable management of land systems (Artist: M. Volk). The main task of balancing different trade-offs, such as between various SDGs, by the artistic guy in the center of the picture, mostly model-based (c.f. sign), has to cope with various challenges (smaller cartoons in different world regions): deforestation, invasive species (e.g. South America), water scarcity, high-tech agriculture, global trade (e.g. North America); renewable energies and bio-based economies, global-trade (e.g. Europe), large scale land acquisitions, mining and resources extraction (e.g. Africa), urbanization (e.g. East Asia), mining and resources extraction, invasive species (e.g. Australia)).

There is a predominant paradigm that an improved understanding of the system of interest, here land systems, is key to improve decision making. However, despite a significant increase in our understanding of land system dynamics over the past two decades, the uptake and integration of scientific knowledge into decision-making processes remains limited (Kirchhoff *et al* 2013). This is because decision-making only partly relies on well-established scientific knowledge. Of equal importance are the underlying value systems of the involved decision-makers, beneficiary and stakeholders as well as the governance system and power structures in which decision can be taken, namely rules, values and knowledge (rvk), c.f. Goddard *et al* (2016). Consequently, a simplistic focus on generating more understanding of land system dynamics, will likely in itself be insufficient to foster sustainable land management.

1
2 Moving towards alternative approaches to science-policy interactions, such as co-
3 production (Mauser et al 2013), could increase the relevance and usability of land-use
4 science for society and decision-making. With respect to global land *governance*, new
5 emerging processes such as large-scale land acquisition or spill-off and offsite-effects
6 (Carter *et al* 2017, Pascual *et al* 2017, Seppelt *et al* 2011) pose challenges to land
7 management which is mostly implemented through law, rule or incentives at the local to
8 regional scale. Surprisingly, large-scale land acquisitions are not an issue in global scale
9 agro-economic models (Debonne *et al* 2018). A proper representation of changes in
10 farming structure, including their underlying social, economic and political drivers, is
11 important to be able to analyse the environmental, economic and social impacts of such
12 changes and the ways in which these new modes of land governance impact on the
13 relations between global and local processes. The limitation of the available land surface
14 and the limitation of its goods and services produced simply suggests that novel ideas to
15 govern land as global commons are required (Seppelt *et al* 2014, Creutzig 2017).
16
17
18
19
20
21
22
23
24
25
26

27 This focus collection also contrasts two different conceptual approaches to the *synthesis*
28 *of place-based research results*: (a) global-scale analysis and modelling, that builds on the
29 basic assumption to fully capture global processes related to land use and (b) linkage of
30 a variety of locations studied as different case studies. While global trade models are
31 limited with respect to spatial scale but also with respect to the commodities captured, a
32 similar limitation holds for the synthesis of place-based results. For the latter, concepts
33 like tele-coupling, off-site effects or spill-over emerge quite logically (Pascual *et al* 2017,
34 Liu *et al* 2015, Seppelt *et al* 2011). Although tele-coupling is well conceptualized,
35 operationalization in research methods is still challenging. The literature is full of local
36 case study evidence of potential impacts of emerging value chains and the role of
37 market-based commodities and tele-coupled land management (Lenzen *et al* 2012).
38 However, these local insights are poorly coupled to larger scale assessments and life
39 cycle analysis (LCA) where impacts are only considered 'on average' ignoring the
40 importance of local land systems as determinants of the impacts of these global
41 relations.
42
43
44
45
46
47
48
49
50
51
52
53

54 For developing future perspectives on sustainable land management based on scenario
55 approaches a better integration of feedbacks is needed, c.f. Delzeit *et al* (2018). Gaps still
56 relate to understating land use intensity, landscape homogenization and the feedback
57 between landscapes, agricultural production and biodiversity of managed landscapes
58 (Seppelt *et al* 2016, Verburg *et al* 2016), specifically as humans shape emerging or novel
59
60

ecosystems. Two understudied feedbacks pose major challenges for future global land systems research. First, the mutual dependence between biodiversity and agricultural production is understudied in global studies and models: Biodiversity is negatively affected through land-use intensification, which is mostly applied to boost yields.

240 Maintaining yields on a high level, however, requires various facets of biodiversity for support of important ecosystem functions such as nutrient cycling, biocontrol or pollination (Seppelt *et al* 2016). Research for embedding these feedbacks quantitatively in global scale models is advancing and could become crucial for global assessments in the near future (Rosa *et al* 2016).

245 Second, the feedback between commodity production and consumption are also understudied. Usually demand trajectories are predefined, such as by predefined scenarios, e.g. Delzeit *et al* (2018). Jevons paradox-like, rebound phenomena, which denote the increasing demand for a resource after establishing a more resource efficient production method (Alcott *et al* 2005), are mostly neglected in today's scenarios analysis. This might hamper understanding of rebound-effects and probably leads to overly positive estimates on certain scenarios.

Given the limited land resources available and multiple competing claims on these resources sustainable land management should also include sustainable consumption (Scherer and Verburg 2017). While sustainable consumption is also one of the SDGs it is hardly related to land management. Recent work of Alexander *et al* (2016) shows the strong impacts of consumption and value-chain losses on agricultural production, indicating the potential reduction on land resources that can be achieved through improved consumption and value-chain management.

260 This focus collection provides several contributions in the fields of land system science to the development of concepts, models and tools for sustainable land management. To advance beyond the current state of the art, future research directions need to address a diversity of topical challenges such as poverty reduction, large scale land acquisition, global feedbacks of agricultural production and biodiversity. While research questions can be developed easily, we acknowledge that further research needs shall not hamper action with respect to lowering pressure on the environment by all possible means.

265 Research needs are no excuse for inaction (Voinov *et al* 2014).

Box 1: Outstanding questions of the emerging question in sustainable land management

Enhancing understanding of the diversity of land systems

- Are the correct drivers addressed for investigating solutions on sustainable land management, considering the knowledge, values and rules define the decision context?
- How to capture countries activities and characteristics properly to account for emerging issues such as large-scale land acquisition, or long-distance externalization of effects within global agro-economic models?
- What are the options to govern land as global commons?

Synthesis of place-based research results

- Which are the next steps to enable global agro-economic models to address a larger set of commodities, different land-holding systems, capture nutrient cycling and provide sufficient information on food security question on a finer spatial resolution?
- How can tele-coupling concept be operationalized in research to better underpin and embed life cycle analysis in global relations?
- Which data gaps should be closed to better account for local variations in the socio-economic context of sustainable land management?

Future perspectives and new scenarios

- How to implement the mutual feedback of biodiversity and agricultural production in today's global model system estimation global agricultural yields and estimate optimum intensification levels?
- To what extent do concepts like sustainable intensification that claim to have synergies between SDGs really have potential, what are the trade-offs hidden in these systems and in what local context are such concepts applicable?
- How can integrated scenarios capture the links between production and consumption, rebound effects and Jevons paradox?
