## ABSTRACT

To support their growth in a competitive environment and cause pathogenesis, bacteria have evolved a broad repertoire of macromolecular machineries to deliver specific effectors and toxins. Among these multiprotein complexes, the type VI secretion system (T6SS) is a contractile nanomachine that targets both prokaryotic and eukaryotic cells. The T6SS comprises two functional sub-complexes: a bacteriophage-related tail structure anchored to the cell envelope by a membrane complex. As in other contractile injection systems, the tail is composed of an inner tube wrapped by a sheath and built on the baseplate. In the T6SS, the baseplate is not only the tail assembly platform, but also docks the tail to the membrane complex and hence serves as an evolutionary adaptor. Here we define the biogenesis pathway and report the cryo-EM structure the wedge protein complex of the T6SS from Enteroaggregative *Escherichia coli* (EAEC). Using an integrative approach, we unveil the molecular architecture of the whole T6SS baseplate and its interaction with the tail sheath, offering detailed insights into its biogenesis and function. We discuss architectural and mechanistic similarities but also revealed key differences with the T4 phage and Mu phage baseplates.

## INTRODUCTION

The bacterial Type VI secretion system (T6SS) is one of the key players for microbial competition, and an important virulence factor during bacterial infections. This versatile nanomachine delivers a wide arsenal of effector proteins directly into prokaryotic and eukaryotic target cells<sup>1-4</sup>. T6SS anti-bacterial activities promote privileged access to the niche, to nutrients or to DNA. In most cases, T6SS causes damage within competitor bacterial cells and therefore participates in the reshaping of bacterial communities such as the

49 microbiota<sup>5,6</sup>. In addition, some T6SS confer anti-host capabilities, *e.g.* phagocytosis  
50 inhibition, by remodelling the host cell cytoskeleton<sup>7-10</sup>.

51 The T6SS belongs to the broad family of contractile injection systems (CIS), that includes  
52 bacteriophages, high-molecular-weight tailocins such as R-pyocins, and specific *apparati*  
53 necessary for the establishment of symbiosis or for the induction of morphological changes<sup>11-</sup>  
54<sup>16</sup>. All these structures comprise a common core: the tail. CIS tails are composed of an inner  
55 tube wrapped by a sheath built under an extended, metastable conformation on an assembly  
56 platform, the baseplate. The T6SS tail tube/sheath is a hundred-nanometer-long cytoplasmic  
57 structure. It is made of TssB/C subunits that polymerize to form the contractile sheath<sup>17,18</sup>,  
58 which surrounds the attacking arrow composed of an inner tube of stacked Hcp hexameric  
59 rings<sup>19,20</sup> tipped by the trimeric VgrG puncturing spike<sup>21</sup>. Various signals, such as contact  
60 with the target cell, chemical signals released by competitor or kin cells, response to attacking  
61 cells or conjugative transfer, induce structural rearrangements of the sheath leading to its  
62 contraction and to the propulsion of the Hcp-VgrG arrow into the target cell<sup>22-25</sup>. Assembly  
63 of the tail tube/sheath is initiated on the baseplate. In addition to controlling sheath extension,  
64 the baseplate also serves to trigger sheath contraction. During T6SS biogenesis, the baseplate  
65 docks to a trans-envelope complex<sup>17,26-28</sup> composed of TssJ, TssL and TssM<sup>29,30</sup>. By  
66 connecting the tail to the membrane complex and initiating tail tube/sheath polymerization,  
67 the baseplate is a central piece of the T6SS machinery. In addition, by binding cargo effectors  
68 through VgrG, the T6SS baseplate also serves as an effector-sorting platform<sup>2,3,31</sup>.

69 CIS baseplates comprise a minimal core of five proteins that share homology with the  
70 prototypical T4 phage gp6, gp7, gp25, gp53, and gp27 proteins<sup>11</sup>. Gp6, gp7, gp25 and gp53  
71 assemble into a unit called wedge<sup>32</sup>. Biogenesis of the baseplate occurs by the polymerization  
72 of six wedges around the central gp27 hub<sup>32,33</sup>. The T6SS baseplate is composed of five  
73 essential subunits: TssE, TssF, TssG, TssK and VgrG<sup>27</sup>. TssE is a structural homologue of  
74 gp25<sup>34</sup> and has been recently identified as the sheath initiator<sup>35</sup>; TssF shares a homology  
75 with the N-terminal region of gp6, whereas TssG has been proposed to fulfill the role of gp7  
76 or gp53<sup>27,36</sup>. VgrG is a chimeric protein in which the gp27 hub is fused to the OB-fold/ $\beta$ -  
77 helix needle of gp5<sup>7,21</sup>. TssF and TssG interact tightly and stabilize each other<sup>27</sup>. TssK  
78 interacts with the TssFG complex<sup>27,37</sup>. Taylor *et al.* recently reported the purification of the  
79 TssKFG complex bound to TssE<sup>36</sup>. Hence, it is proposed that TssFG, TssKFG and TssKFGE  
80 are assembly intermediates of the T6SS baseplate and have structural and functional  
81 homologies to the bacteriophage wedges. In agreement with this hypothesis, contacts between  
82 the TssFG complex and VgrG have been identified<sup>27</sup>, suggesting that as in the T4 phage  
83 biogenesis pathway, TssKFGE wedges could polymerize around the VgrG hub to form a  
84 hexagonal baseplate. The baseplate is docked to the membrane complex mainly by  
85 interactions between TssK and both the cytoplasmic domains of TssL and TssM<sup>26,27,38,39</sup>. The  
86 crystal structure of TssK recently revealed that it shares a similar structural architecture with  
87 Siphoviridae phage receptor binding proteins and uses the membrane complex as a receptor to  
88 anchor the tail<sup>28</sup>.

89 Besides the critical role of the T6SS baseplate complex, we still lack crucial  
90 information on its biogenesis and architecture. Recently, the 8.5-Å-resolution structure of an  
91 assembled T6SS baseplate revealed its overall shape<sup>35</sup>, but did not provide detailed  
92 information on the molecular organization of the subunits. Here we used a hybrid approach  
93 combining cryo-electron microscopy (cryo-EM), biochemical analysis, native mass  
94 spectrometry, evolutionary covariance, and molecular modelling to unveil the assembly  
95 pathway of the T6SS baseplate and report the detailed structure of the TssKFGE baseplate  
96 wedge complex from the model organism Enteroaggregative *Escherichia coli* (EAEC). The  
97 structure highlights unanticipated structural and functional conservation with orthologous  
98 bacteriophage proteins. Finally, we fit the atomic model of the T6SS wedge complex into the

99 recent reconstruction of the fully assembled baseplate<sup>35</sup> to provide an unprecedented  
100 structural and functional understanding of the T6SS baseplate.

101

## 102 RESULTS

103

### 104 *Biogenesis of the T6SS baseplate.*

105 Previous fluorescence microscopy studies have monitored T6SS baseplate dynamics using a  
106 chromosomally-encoded and functional fusion protein between TssK and the super-folder  
107 GFP (TssK<sub>sf</sub>GFP) in EAEC<sup>27</sup>. TssK<sub>sf</sub>GFP assembles fluorescent foci that form independently of  
108 the tail sheath and that are recruited to the membrane complex<sup>27</sup>. To gain further insights into  
109 the genetic requirements for TssK<sub>sf</sub>GFP foci formation, we observed TssK<sub>sf</sub>GFP in T6SS non-polar  
110 gene deletion mutants corresponding to T6SS wedge potential components (see Strains  
111 construction in Methods). Fluorescence microscopy recordings demonstrate that TssK<sub>sf</sub>GFP foci  
112 formation depends on TssF and TssG but is independent of TssE (**Fig. 1a & Supplementary**  
113 **Fig. 1**). When monitored into additional baseplate mutants, we observed that these foci form  
114 independently of TssA but require VgrG (**Fig. 1a**). Therefore, these foci likely represent  
115 TssK<sub>sf</sub>GFPFG complexes bound to VgrG.

116 To provide further information on the composition of the T6SS wedge, we investigated the  
117 formation of stable TssK<sub>sf</sub>GFP-containing subcomplexes in EAEC cells by native PAGE.  
118 Native PAGE profiles immunodetected with anti-GFP antibodies revealed the presence of a  
119 high-molecular weight complex (HMWC) with a size of ~ 800 kDa (**Fig. 1b**). This complex  
120 does not contain TssE, TssA, VgrG and TssM and likely corresponds to TssK<sub>sf</sub>GFPFG since (1)  
121 it disappears in the absence of *tssF* or *tssG*, (2) a HMWC of a comparable size is observable  
122 upon pull-down of TssK<sub>sf</sub>GFP co-produced with TssF and TssG in the heterologous host *E. coli*  
123 BL21(DE3), and (3) analysis of this HMWC on denaturing SDS-PAGE reveals the presence  
124 of TssK<sub>sf</sub>GFP, TssF and TssG (**Fig. 1b**).

125 Taken together, the fluorescence microscopy and native-PAGE results, and the previous  
126 reports of TssKFG and TssKFGE complex purifications in *Serratia marcescens* and *E. coli*  
127<sup>36,37</sup>, suggest that the TssKFG complex represents a stable intermediate during T6SS baseplate  
128 biogenesis. We therefore propose that T6SS baseplate biogenesis starts with the formation of  
129 the TssKFG complex and then proceeds with the polymerization of TssKFG building units  
130 around the VgrG hub. The observation that TssE is not required for TssKFG-VgrG complex  
131 formation, further suggests that TssE binds to the TssKFG either prior to or after its  
132 polymerization. This assembly pathway is comparable to that of the minimal phage baseplate,  
133 in which gp25 attaches to the baseplate either after completion of the gp10-7-8-6-53 complex  
134<sup>40</sup> or at a later stage, triggering the polymerization of the contractile sheath<sup>41</sup>.

135

### 136 *Interaction network within the T6SS baseplate*

137 To gain further insight into the connectivity network between the T6SS baseplate  
138 components, we performed a systematic biochemical pull-down assay (**Supplementary Fig.**  
139 **2a-e**). This approach confirmed or revealed a number of contacts including interactions  
140 between TssG and TssF, TssE, and TssK (**Fig. 1c**). We then tested whether intermediate sub-  
141 complexes, suggested by the assembly pathway defined above, could be purified. In  
142 agreement with the proposed assembly pathway, we succeeded to pull-down biogenesis  
143 intermediate complexes consisting of TssFG, TssKFG and TssKFGE (**Supplementary Fig.**  
144 **2a-b**). Based on these data, we propose that the TssKFGE sub-complex represents the T6SS  
145 equivalent of the bacteriophage wedge unit (TssFGE), bound to the TssK membrane complex  
146 adaptor.

147

### 148 *Purification, stoichiometry and cryo-EM structure of a T6SS wedge complex*

149 To biochemically and structurally characterize T6SS baseplate building units, purification  
150 tags were positioned on the *EAE*C TssK, TssF, TssG and TssE proteins, at locations that do  
151 not interfere with their function. Upon overproduction in BL21(DE3), the TssKFG and  
152 TssKFGE complexes were isolated by affinity chromatography followed by gel filtration  
153 (**Fig. 1d & Supplementary Fig. 3a**). To gain further insight into the architecture of the T6SS  
154 baseplate wedge assembly, the isolated TssKFGE complex was visualized by cryo-electron  
155 microscopy (cryo-EM). The 4.6-Å resolution, three-dimensional reconstruction (**Fig. 2a**)  
156 shows that the TssKFGE complex displays an intricate architecture with no apparent  
157 symmetry. It can be, however, divided into distinct parts: (1) two wing-like structures  
158 wrapping a central backbone and (2) a root-like structure with two identical entities  
159 displaying apparent C3 symmetry linked to the first part by a thin stalk (**Fig. 2b**).

160 In order to properly interpret the density map, we first sought to determine the stoichiometry  
161 and stability of the TssKFGE complex using native mass spectrometry (see **Supplementary**  
162 **data for more details**) (**Supplementary Fig. 3b, 3c and 3d**). We determined that the  
163 TssKFGE complex comprises 6 TssK, 2 TssF, 1 TssG and 1 TssE subunits (TssK<sub>6</sub>F<sub>2</sub>G<sub>1</sub>E<sub>1</sub>;  
164 theoretical mass: 498,905 Da).

165 Based on this stoichiometry, we identified densities that could accommodate the two TssK  
166 trimers, for which the crystal structure has been recently determined<sup>28</sup>. The two trimers of  
167 TssK readily fit in the density map corresponding to the root-like structure (**Fig. 2c**). The  
168 remaining densities corresponding to the stalk and wing-like domains would contain TssF,  
169 TssG and TssE. Careful inspection and segmentation of the map lead us to determine that the  
170 wing-like domains are formed by two similar densities (**Fig. 2d-f**) that would correspond to  
171 TssF. The remaining density, bridging TssK and TssF, would be attributed to TssG (**Fig. 2d**  
172 **and Fig. 2g**), while TssE would be located at the tip of the complex (**Fig. 2h**)  
173 (**Supplementary data**).

174

### 175 ***Structural analysis of the T6SS wedge complex***

176 *Biochemical and evolutionary covariance analyses establish TssG as a central structural*  
177 *component of the T6SS wedge complex* – Data described above unveil TssG as the central  
178 component of the baseplate. Unfortunately, no structural information is available for TssG.  
179 We therefore used residue contact predictions based on evolutionary covariance<sup>42</sup> to  
180 determine the TssG domain organization. This analysis identified two putative independent  
181 domains in TssG, TssG-D1 (amino-acids 15-140) and TssG-D2 (amino-acids 180-300)  
182 (**Supplementary Fig. 4a**). Pull-down assays with these two domains demonstrated that TssG-  
183 D1 interacts with TssE, whereas TssG-D2 interacts with TssK and TssF (**Fig. 1c &**  
184 **Supplementary Fig. 4b-c**).

185 To further characterize the relative importance of these two domains *in vivo*, we performed a  
186 dominant-negative approach by “small domain interference” (SDI)<sup>43,44</sup> (**Supplementary**  
187 **data**) (**Supplementary Fig. 5a-e and Supplementary Fig. 6a-b**) and confirmed that TssG-  
188 D2 has a central role for T6SS wedge assembly. We then used the EVcomplex program<sup>45</sup> to  
189 predict inter-molecular contacts between TssG and TssK using evolutionary covariance  
190 analysis (see Methods section) (**Supplementary Fig. 6a**). Two TssG-D2 residues, Pro-240  
191 and Leu-255, corresponding to predicted TssK-TssG-D2 interfacial residue pairs with the  
192 highest scores, were substituted, to alanines (P240A and L255A and P240A-L255A) and  
193 assayed by SDI in interbacterial competition experiments (**Supplementary Fig. 6b**)

194

195 *Structure of the TssK trimers* – The resolution of the density map corresponding to the two  
196 TssK trimers was between 3.8 and 33 Å (**Fig. 2a**). This level of detail allowed us to obtain a  
197 full atomic model of TssK (**Fig. 3a**) (**Supplementary Fig. 7a-b**) (see Methods for details).  
198 As described previously, TssK can be divided into four parts from its N- to C-terminus: an N-

199 terminal  $\alpha$ -helix, a  $\beta$ -sandwich domain (also named shoulder domain), a 4  $\alpha$ -helix bundle  
200 domain (also named neck domain) and a C-terminal  $\alpha/\beta$  domain (also named head domain)  
201 (**Fig. 3a**). When compared with the published TssK crystal structure, with the exception of the  
202 relative position of the C-terminal domain, the overall structure of the TssK protomer is  
203 conserved in the T6SS wedge. The cryo-EM and crystal structures could be superimposed  
204 with an RMSD of 1.14 Å (**Supplementary Fig. 7a-b**).

205 In the wedge complex, the two TssK trimers are in contact with each other and interact with  
206 TssG. The TssK inter-protomer contacts define a large interacting surface of 2,700-2,800 Å<sup>2</sup>  
207 stabilized by hydrogen bonds and salt bridges<sup>46</sup>. The newly built loops 1-18 and 130-143  
208 participate to this interface by forming contacts with the neighbouring protomer. Remarkably  
209 the three loops located between residues 105 to 145 define a triangle that encompasses the  
210 loop 1-18 and  $\alpha$ 1 helix bundle at the centre of the trimer (**Supplementary Fig. 7c**), forming a  
211 flat triangular surface at the top of each TssK trimer, which contacts the rest of the wedge  
212 complex. This triangular surface is delineated by a polar scaffold made of the strands 105-143  
213 and loops around a hydrophobic patch made of part of the loop 1-18 (residues 12-14).

214

215 *Structure of TssG and TssF* –The resolution of the densities corresponding to TssG and TssF  
216 varied between 4.3 and 8 Å. Since there was no homologous structure of TssG and TssF  
217 available, we built the structure of these proteins de novo helped by a priori knowledge on  
218 their topology, secondary structure, and intra-molecular contacts predicted from evolutionary  
219 covariance. We devised an iterative pipeline to integrate all this data (prior data and pipeline  
220 are described in Methods sections "Evolutionary Covariance Analysis", "TssKFGE model  
221 fitting and de novo tracing", as well as **Supplementary Fig. 12**). Eventually, we were able to  
222 obtain an atomistic model of this part of the complex, in which most of the sequence of the  
223 proteins could be assigned to the cryo-EM density and secondary structure elements could be  
224 identified (**Fig. 3c-d**).

225 TssG is made of two globular domains, head and body/feet, separated by a neck domain (**Fig.**  
226 **3c**). The N-terminal neck domain, corresponding to TssG-D1, is made of two short helices  
227 and loops, whereas the C-terminal body domain, corresponding to TssG-D2, folds as an  $\alpha/\beta$   
228 domain comprising a four-strand  $\beta$ -sheet and three helices (**Fig. 3c**). On each side of the  $\beta$ -  
229 sheet, two loops extend to form the two-foot domains (foot1 and foot2). The last strand of the  
230 sheet extends into a C-terminal extension of 17 residues.

231 TssF is a globular protein with an N-terminal elongated extension called antenna (**Fig. 3d**).  
232 The antenna is made of 2 helices while the C-terminal globular domain can be divided into 5  
233 sub-domains: domain 1 (TssF-D1) is a  $\beta$ -sandwich flanked by loops containing short helices;  
234 domain 2 (TssF-D2) is a  $\beta$ -sandwich; domain 3 (TssF-D3) is an  $\alpha$ -helical domain and  
235 comprises 3 short helices; domain 4 (TssF-D4) is an  $\alpha/\beta$  domain composed of one helix and a  
236 4-strand  $\beta$ -sheet. The last domain, named branching domain (TssF-BD), is a  $\beta$ -sandwich that  
237 is formed by strands that link the antenna with TssF-D1 (three strands of the fold), TssF-D1  
238 with TssF-D2 (one strand of the fold) and TssF-D2 with TssF-D3 (two strands of the fold). As  
239 previously noted from the two wing densities, the structures of the two TssF proteins (TssFa  
240 and TssFb) are superimposable with the exception of the two antennas, which are in two  
241 distinct orientations (**Supplementary Fig. 7d**).

242

243 *Structure of the TssFG complex* – TssG and the two copies of TssF (TssFa and TssFb) are  
244 assembled to form the pyramidal cap of the T6SS wedge complex (**Fig. 3e**). TssG-D1 forms  
245 an heterotrimeric helical bundle with the two TssF antennas (**Fig. 3e-f**). Interestingly, the fold  
246 of the TssG body is similar to the TssF-D1 domain (**Supplementary Fig. 7e**), and these three  
247 domains define a triangular assembly at the base of the T6SS wedge complex (**Fig. 3f**).  
248 Together with the heterotrimeric helical bundle, this structure forms the heterotrimeric

249 scaffold of the TssFG complex (**Fig. 3g**). The D2, D3, D4 and BD domains from TssFa and  
250 TssFb form the wing-like domains on both sides of the trimeric scaffold (**Fig. 3G**). TssG is  
251 the central backbone of the wedge complex: it interacts with both TssFa and TssFb all along  
252 its structure, whereas TssFa and TssFb have very few points of contact between each other.  
253

254 *The TssK-TssFG interface* – The interaction of the two TssK trimers with the TssFG complex  
255 is mainly mediated through the two TssG-D2 foot domains (**Fig. 3h-i**). The TssG foot1  
256 domain (residues 227-242) interacts with residues 10-15 of the three TssK protomers of the  
257 TssK1 trimer (**Fig. 3i, upper panel; Supplementary Fig. 7f**). The situation is more complex  
258 for the TssK2 trimer: residues 10-15 of the three TssK2 protomers and 138-143 of one  
259 monomer (green) make contacts with the TssG foot2 domain (residues 303-322), and the  
260 TssG C-terminal extension (residues 345-347) makes contact with residues 116-117 of one  
261 TssK monomer (green in **Fig. 3i, lower panel; Supplementary Fig. 7g**), whereas the TssG  
262 foot1 domain (residues 221-224) also contributes to the stabilization of the edifice by  
263 interacting with the loop 116-120 in TssK2.  
264

### 265 *Molecular model of the T6SS baseplate*

266 Recently, an 8-Å-resolution cryo-EM structure of the *V. cholerae* T6SS baseplate associated  
267 to a non-contractile sheath was reported<sup>35</sup>. Although no density could be attributed to specific  
268 baseplate components, densities corresponding to the Hcp tube and VgrG spike are clearly  
269 visible<sup>35</sup>. We used the deposited map (EMD-3879) to build a molecular model of the entire  
270 T6SS baseplate from EAEC (See Methods for more details) (**Fig. 4a**) (**Supplementary Fig.**  
271 **8a-b**).

272 The fully assembled T6SS baseplate is 337 Å in diameter and 180 Å in height (**Fig. 4a**).  
273 These dimensions are compatible with the densities attributed to the baseplate complex in the  
274 cryotomogram of the *Myxococcus xanthus* T6SS<sup>47</sup>. The rings formed by TssFG (wedge ring)  
275 and TssK (connector ring) are 100 Å and 110 Å in height respectively (**Fig. 4a**). Within the  
276 wedge ring, the individual wedge complexes are organized side by side. Their main axis,  
277 along the helical bundle, makes a 30° angle with the symmetry axis of the ring (**Fig. 4b**). The  
278 lateral contacts are mediated by interactions between TssFa and TssFb from two adjacent  
279 wedge complexes (**Fig. 4b**). Overall, the two protomers are perpendicular to each other,  
280 TssFa wrapping the adjacent TssFb (**Fig. 4c**). In detail, the TssFa D1 and BD domains interact  
281 with the antenna of the adjacent TssFb whereas TssFa D3 and D4 domains interact with the  
282 adjacent TssFb D3 and BD domains (**Fig. 4c**). To a lesser extent, contacts also exist between  
283 two adjacent TssFb, two adjacent TssFa, and TssG and TssFb (**Fig. 4b**). In the TssK ring, one  
284 TssK protomer, belonging to the TssK1 trimer (grey density), interacts with two TssK  
285 protomers belonging to the TssK2 trimer in the adjacent wedge complex (green and brown  
286 densities) (**Fig. 4b**). Finally, there are contacts between TssFa and two TssK protomers from  
287 the TssK2 trimer from the adjacent wedge complex (**Fig. 4b**).

288 The D1, D2 and BD domains of the TssFa proteins delineate the inner surface of the wedge  
289 ring, defining a chamber named TssF chamber (**Fig. 4a**). Together with the wedge ring, the  
290 connector ring defines another chamber, named the TssK chamber. Both chambers are  
291 separated by a central constriction of ~ 40 Å in diameter due to TssFa D2 and BD domains  
292 (**Fig. 4a**). Fitting of the VgrG crystal structure in the assembled baseplate reveals that the  
293 TssFa chamber accommodates perfectly the gp27-like hub domain of VgrG while the VgrG  
294 gp5-like spike crosses the TssFa constriction and extends into the TssK chamber  
295 (**Supplementary Fig. 8b**). In agreement with previous bacterial two-hybrid data<sup>27</sup>, this  
296 reconstruction suggests that the interactions between VgrG and the baseplate are exclusively  
297 mediated by TssFa-VgrG interactions (**Fig. 4c; Supplementary Fig. 8b**).

298 Surprisingly, there is no density in the cryo-EM map of the *V. cholerae* baseplate that could  
299 accommodate TssE. All the densities seen in the baseplate region of this map could be  
300 attributed to TssK, TssG or TssF. The rest of the map corresponds to the VipAB sheath, the  
301 Hcp tube, and the VgrG spike. The fact that TssE is invisible in this map could be explained  
302 by some degree of flexibility of the protein within the structure after sheath assembly.  
303 However, based on the location of TssE in the cryo-EM of the EAEC TssKFGE complex,  
304 TssE elegantly fits in a space between the wedge helical bundle and TssB in the model of the  
305 assembled baseplate (**Fig. 4d**).

306

307

## 308 **DISCUSSION**

309

### 310 ***The T6SS baseplate - sheath connection***

311 The TssFGE wedge ring interacts directly with the sheath structure. A homology model of the  
312 EAEC extended sheath was fitted into the molecular model of the baseplate attached to the  
313 sheath. Our model suggests that the main contacts are established between the TssFb D2  
314 domain and the TssBC N-terminal antenna. In addition, the TssG head domain and TssE  
315 likely stabilize the interaction between the sheath and the baseplate (**Fig. 4c-d**) by interacting  
316 with the C-terminal domain of TssB as recently proposed<sup>48</sup>.

317

### 318 ***The T6SS baseplate - membrane complex connection***

319 A number of contacts have been identified between the baseplate components and the  
320 cytoplasmic domains of the TssL and TssM inner membrane proteins<sup>26-28,38,39</sup>. The main  
321 contacts involve binding of TssK to both TssL and TssM<sup>26,28,39</sup> but additional contacts,  
322 notably between TssL and TssE, and between TssM and TssG have been reported<sup>27,39</sup>. While  
323 these contacts could not be explained by the current structure, it is known that structural  
324 rearrangements occur in the bacteriophage T4 upon sheath contraction<sup>49-51</sup>. If such  
325 conformational changes occur in the T6SS baseplate, different contacts may stabilize the  
326 interaction of the baseplate with the membrane complex after sheath contraction.

327 However, the position of the TssK connector ring confirms that TssK is the major determinant  
328 for mediating baseplate docking to the membrane complex. We have recently shown that the  
329 TssK<sub>S</sub> domain shares homology with siphophage receptor-binding proteins, whereas it has  
330 evolved a specific C-terminal head domain, TssK<sub>H</sub>, to use the membrane complex as a  
331 receptor<sup>28</sup>. In agreement with these results, the orientation of the TssK trimers in the  
332 baseplate places the TssK<sub>S</sub> domains in contact with the TssFG cap complex (**Fig. 2c**), whereas  
333 the TssK<sub>H</sub> domains extend in the opposite direction compared to the sheath, at the predicted  
334 location of the membrane complex (**Fig. 4a**).

335

### 336 ***Comparison between T6SS and bacteriophage baseplates.***

337 ***(A detailed version of this section is provided in supplementary information)***

338

339 While our data confirms a strong analogy between the T6SS baseplate and the “simple  
340 contractile baseplate” from the Mu phage, it is also clear that T6SS and T4 phage wedge  
341 components are structurally related to each other. Indeed, the structures of TssF and TssG  
342 revealed that they are gp6 and gp7 counterparts in the T4 phage baseplate (**Fig. 5a-b**)  
343 (**Supplementary Fig. 9a-b**). Interestingly, a detailed analysis of both baseplate architectures  
344 revealed that, while inter-wedge contacts are different in the T4 and the T6SS baseplates (**Fig.**  
345 **4b & Fig. 5c**), interactions with the central spike and the contractile sheath are quite well  
346 conserved (**Fig. 5c-d, Supplementary Fig. 9c-e**). Finally, this comparison revealed how the

347 apical part of the each baseplate is structurally specialized to interact with different targets  
348 (Fig. 5c-e).

349

350 *Assembly mechanism and stability of of the T4 and T6SS baseplates*

351 *(A detailed version of this section is provided in supplementary information)*

352

353 While the T4 bacteriophage wedge complex appears to be transient, the T6SS wedge complex  
354 is stable, as shown by the isolation of TssKFG or TssKFGE complexes in EAEC, *S.*  
355 *marcescens* and uropathogenic *E. coli* (this work; <sup>36,37</sup>). By contrast, the fully assembled T4  
356 phage baseplate is much more stable than the T6SS baseplate, since we did not succeed to  
357 purify the T6SS hexagonal baseplate. This higher stability of a preformed T6SS baseplate  
358 intermediate may reflect an adaptation to the secretion process. Delayed polymerization of the  
359 wedge around the VgrG hub and fast recycling of the wedge complexes might be necessary  
360 during each secretion cycle

361

362

363

### 364 **Concluding remarks**

365

366 In this work, we provide an unprecedented functional and structural study of the T6SS  
367 baseplate building block, the wedge complex. Due to the conservation of T6SS wedge  
368 complexes among pathogenic bacteria, the atomic model of the TssKFGE complex will  
369 facilitate the design of anti-T6SS compounds targeting hot spots of the baseplate assembly,  
370 paving the way towards new therapeutic avenues to replace or help classical antibiotherapies.

## 505 **Figures legends.**

506  
507 **Figure 1. Composition of the T6SS wedges complex.** a. Fluorescence microscopy  
508 recordings showing TssK<sub>s/GFP</sub> localisation in the absence of the TssF, TssG, TssE, VgrG and  
509 TssA proteins. The positions of foci corresponding to fully-assembled baseplates are indicated  
510 by arrowheads. Microscopy analyses were performed independently three times, each in  
511 technical triplicate, and a representative experiment is shown. Scale bars, 1 μm. b. Native 4-  
512 16% gel analysed by Coomassie staining (upper left panel) or immunoblotting using anti-GFP  
513 antibodies (right panel) or anti-GFP, anti-Streptag and anti-FLAG antibodies (lower left  
514 panels). The TssK<sub>s/GFP</sub>-6 × His and TssK<sub>s/GFP</sub>-6 × His-FG produced and purified from  
515 BL21(DE3) cells show the positions of two high-molecular weight complexes (HMWC,  
516 indicated by \* and \*\*). Formation of the higher HMWC is monitored in different *tss* mutant  
517 backgrounds, revealing that the \* and \*\* complexes correspond to a TssK<sub>s/GFP</sub> trimer and  
518 TssK<sub>s/GFP</sub>-TssF-TssG complex, respectively. Native gel experiment was performed  
519 independently three times and a representative experiment is shown. c. Summary of protein-  
520 protein interactions within the TssKFGE complex, as defined by pair-wise pull-down  
521 experiments (see Supplementary Fig. 2 and 4). Arrows indicate interactions between the two  
522 proteins or domains. d. Purification and biochemical characterization of the TssKFGE wedge  
523 complex. Analytical size-exclusion chromatography analysis of the purified TssKFGE  
524 complex (continuous line) on a Superose 6 column, calibrated with 43-, 75-, 158-, 440- and  
525 660-kDa molecular mass markers (dotted lines). The molecular mass of each marker (in  
526 kilodaltons) is indicated on the top of the corresponding peak. An arrow indicates the position  
527 of the peak fraction corresponding to the TssKFGE complex. Inset: Purified TssKFGE  
528 complex subjected to sodium dodecyl sulfate 12.5%-acrylamide PAGE and Coomassie  
529 staining. The different proteins are indicated on the right, whereas molecular weight markers  
530 are indicated on the left. TssKFGE complex purification and analytical size-exclusion  
531 chromatography analysis experiments were performed at least three times and a representative  
532 result is shown.  
533

534 **Figure 2. Cryo-EM density map of the TssKFGE wedge complex.** a. Surface  
535 representation of the composite cryo-EM density map of the TssKFGE complex. The maps  
536 corresponding to the root and stalk/wings regions were refined separately (see material and  
537 methods section). Dimensions and labelling of the various densities of the complex are  
538 shown. b. Schematic representation of the different densities of the TssKFGE map. c. Two  
539 copies of the TssK trimer crystal structure (PDB:5M30; <sup>28</sup>) can be fitted in the density  
540 corresponding to the “roots”. d. Segmentation of the stalk and wing regions of the density  
541 map (shown in the same orientation than B). Two regions forming the wings (in cyan and  
542 blue) interact with a central backbone (in yellow). e-f. Densities corresponding to the two  
543 wing sub-regions, positioned in the same orientation (e) and superimposed (f). Each of these  
544 densities corresponds to one TssF subunit. g. The density corresponding to the central  
545 backbone is displayed alone. It corresponds to one TssG subunit. h. At lower density  
546 threshold, a density appears at the tip of the TssFG density. A TssE homology model could be

547 fitted into this new density with a correlation of 0.870. The scale bars correspond to 25 Å for  
548 each panel.

549

550 **Figure 3. Structure of the TssKFGE complex.** **a.** Ribbon diagram of one TssK protomer.  
551 The structure can be divided into 4 parts, from N- to C-terminus: N-terminal helix (residues 1-  
552 42, blue), shoulder domain (residues 43-185, cyan), neck domain (residues 186-312, green)  
553 and head domain (residues 313-444, red). **b.** Ribbon diagram and surface representation  
554 (transparent) of one TssK trimer viewed from the side (top panel) and from the bottom  
555 (Bottom panel). Each TssK protomer is colored in beige, dark green and brown. **c.** Ribbon  
556 diagram of the TssG protomer. The structure can be divided into 6 parts, from N- to C-  
557 terminus: N-terminal head domain (residues 8-144, blue), neck domain (residues 145-192,  
558 green), body domain (residues 146-215, 252-300 and 331-342, red) and C-terminal extension  
559 (residues 342-356, purple, foot1 (residues 216-252) and foot2 (residues 300-330), in yellow.  
560 **c.** Ribbon diagram of the TssF protomer. The structure can be divided into 6 parts, from N- to  
561 C-terminus: N-terminal antenna (residues 4-82, blue), domain 1 (residues 140-295, green),  
562 domain 2 (residues 304-416, red), domain 3 (residues 453-502, magenta) and domain 4  
563 (residues 503-587, purple). A branching domain connects domains 1, 2 and 3 (residues 83-  
564 139, 296- 303 and 417-452, yellow). **e.** Ribbon diagram of the TssFG complex. It contains  
565 one copy of TssG (yellow) and two copies of TssF, named TssFa (cyan) and TssFb (blue). **f.**  
566 Ribbon diagram of the TssG-TssFa-TssFb trimer scaffold. TssG, TssFa and TssFb are  
567 represented in yellow, cyan and blue respectively. The triangular organization is highlighted  
568 by the red dotted-line triangle. **g.** The TssG-TssFa-TssFb trimer scaffold is decorated by TssF  
569 wing and TssG N-terminal head domains. The trimer scaffold is represented as ribbons  
570 (magenta). The decorations are represented as ribbons and transparent surfaces. The colour  
571 code is the same as in panel e. **h.** Ribbon diagram of the whole TssKFGE wedge complex.  
572 The complex made of TssG (yellow), TssFa (cyan) and TssFb (blue) interacts with two TssK  
573 trimers (TssK1 and TssK2), same color code as in B. **i.** Interaction between TssG foot  
574 domains and TssK trimers. The same color code is used as in B. and E. TssK1 and TssK2 are  
575 depicted in surface rendition and ribbon diagram respectively. TssG antenna and body are  
576 represented as ribbons while the feet are represented as surfaces.

577

578 **Figure 4. Structural model of the EAEC T6SS baseplate.**

579 **a.** Overall view of the interaction between the T6SS baseplate and the TssB/C sheath. The  
580 color code used to identify the various subunits is shown on the left of the panel. Left panel:  
581 surface representation of the model of the EAEC T6SS baseplate in interaction with a model  
582 EAEC sheath. While TssB/C protomers are colored in grey, the TssB/C protomers interacting  
583 with the baseplate are colored in orange. The different parts of the tail (connector ring, wedge  
584 ring, extended sheath) are indicated, as well as the putative location of the membrane  
585 complex. Middle panel: central slice of the complex seen in the left panel. The different parts  
586 of the tail, as well as the two chambers delimited by the TssFa and TssK subunits (TssF and  
587 TssK chamber, respectively) are indicated. Right panel: surface representation of the  
588 baseplate viewed from the membrane complex (top view) and from the sheath (bottom view).  
589 **b.** Interaction surface between two wedge complexes as they are assembled in the baseplate.  
590 The color code used to identify the various subunits is shown on the left of the panel. The  
591 predicted interacting residues between two wedge complexes are colored in red. Left panel:  
592 the two bound wedge complexes as they are assembled in the baseplate. The red dotted lines  
593 represent the baseplate symmetry axis (vertical line) and the wedge complex main axis (tilted  
594 line). Right panel: the same two wedge complexes are split open to reveal the interaction  
595 surfaces between them. The main interfaces are identified. **c.** Ribbon diagram and transparent  
596 surface representation of TssFa-TssFb belonging to two adjacent wedge complexes (main

597 interface between wedge complexes within the T6SS baseplate). TssFa and TssFb are  
598 represented in cyan and blue respectively. Within each subunit, the regions interacting with  
599 VgrG and TssBC are colored in magenta and orange respectively. **d.** Ribbon diagram and  
600 surface representation of the wedge-TssB/C interaction. The color code used to identify the  
601 various subunits is shown on the left of the panel. Top panel: surface representation views  
602 (rotated 180° along the axis) of TssBC bound to the TssFa-TssFb-TssG-TssE complex. The  
603 ribbon diagram of the same complex is shown on bottom.

604

### 605 **Figure 5. Comparison between the T4 bacteriophage and T6SS baseplates.**

606 In all panels, T6SS and T4 bacteriophage representations are shown on left and right,  
607 respectively. For panels **c-e**, the color code used to identify the various subunits or domains is  
608 shown on the left of each panel. **a.** T6SS and T4 bacteriophage trimer scaffolds share the  
609 same structural organization. In the T4 baseplate, the backbone of the wedge domain is made  
610 of a heterotrimeric helical bundle and a trifurcation unit (in purple), which are made of the  
611 gp6/gp7 antennas and of the gp6/gp7  $\alpha/\beta$  domains, respectively. As seen in Fig. 3F, this  
612 organization is conserved in the T6SS baseplate (purple). In gp6, two consecutive  $\beta$ -sandwich  
613 domains following the N-terminal antenna are called the wing domains (green). These  
614 domains resemble the TssF D2, and BD (green). **b.** Same assembly as in **a.**, seen from the  
615 bottom. Both T6SS and T4 bacteriophage wedge complexes contain a trifurcation unit made  
616 of the  $\alpha/\beta$  domains in TssFa-TssFb-TssG and gp6a-gp6b-gp7 respectively. A red triangle  
617 delineates this trifurcation unit. **c.** Top views of the T6SS and T4 bacteriophage baseplates.  
618 For the T4 bacteriophage baseplate, the inner and intermediate baseplate are separated by a  
619 red dotted line. The inter-wedge gp6a/gp6b main interface is indicated. **d.** Bottom views of  
620 the T6SS and T4 bacteriophage baseplates. The domains interacting with the sheath are  
621 indicated and colored in orange. **e.** Side views of the T6SS and T4 bacteriophage baseplates.

622

### 623 **Figure 6. Schematic representation of the T6SS assembly pathway.**

624 Upper panel: schematic representation of the T6SS assembly pathway, starting with the initial  
625 positioning of the membrane complex (MC, blue) (stage 1), the assembly of the wedge  
626 complexes (grey), their polymerization around the VgrG spike (pink), the recruitment of  
627 effectors (light orange skull), and the recruitment of the baseplate (BP) to the MC (stage 2);  
628 and the polymerization of the tail tube/sheath complex (TTC, salmon). A surface  
629 representation of the modeled T6SS baseplate with the extended sheath bound to the  
630 membrane complex is shown on right. OM, outer membrane; PG, peptidoglycan; IM, inner  
631 membrane. Lower panel: from left to right, the TssKFGE wedge structure (same color code as  
632 in Fig. 3); the structure of the assembled T6SS BP (same color code as in Fig. 4) and a  
633 schematic representation of the protein-protein contacts and topology of the fully-assembled  
634 baseplate.

635

636

637

## 638 **SUPPLEMENTARY INFORMATION**

639

640 Supplementary Information includes 19 figures and 3 tables.

641

## 642 **ACKNOWLEDGEMENTS**

643

644 We thank members of the E.C., R.F. research groups, and James Sturgis for helpful  
645 discussions and support, Prof. M. Weigt and Dr. C. Feinauer for useful discussion on  
646 evolutionary covariance, Tru Huynh and Gérald Canet for assistance with the computer

647 clusters at the Institut Pasteur and IECB respectively, Artemis Kosta (Plateforme de  
648 microscopie, IMM, Marseille, France) for providing access to the IMM EM facility, and for  
649 checking the quality of samples by negative stain EM, Armel Bezault for support at the cryo-  
650 EM facility at IECB. Thierry Doan et Leon Espinosa for their helpful support with the  
651 fluorescence microscopy device and analysis. We thank Prof. M. Nilges (Institut Pasteur) for  
652 access to the computer cluster of the ERC project “BayCells”. This work was supported by  
653 the CNRS, the Aix-Marseille Université, the Institut Pasteur, and the INSERM and by grants  
654 from the Agence Nationale de la Recherche (ANR-14-CE14-0006 to E.C.; ANR-17-CE11-  
655 0039 to E.C., ANR-11-EQPX-008 to JCR). Work of Y.C. was supported by an "Ecole  
656 Doctorale" PhD fellowship from the “Fondation pour la Recherche Médicale” (FRM-  
657 ECO20160736014). RF and CR were supported by IDEX Bordeaux through a “chaire  
658 d’excellence” to RF. We acknowledge the European Synchrotron Radiation Facility for  
659 provision of beamtime on CM01 and thank Gregory Effantin and Eazhisai Kandiah for  
660 assistance. F.A. thanks the French Institute of Bioinformatics (IFB; ANR-11-INBS-0013) for  
661 financial support.

662  
663

## 664 **AUTHORS CONTRIBUTION**

665

666 E.D., R.F. and E.C. designed research, assembled results, and wrote the paper with input from  
667 all authors. E.D. and Y.C. performed biochemical experiments and initial negative stain EM  
668 observations. C.R. performed sample preparation for cryo-EM, *de novo* reconstruction, and  
669 structure refinement. C.R. and R.F. analyzed the cryo-EM data and the final structure. C.M.  
670 and M.R. performed MS experiments. Y.C. performed all *in vivo* experiments. R.P. and G.B.  
671 performed method development, and structural modeling; B.B. and F.A. performed structural  
672 modeling. J.C.R. performed design and analysis of MS experiments.

673

## 674 **DECLARATION OF INTERESTS**

675

676 The authors declare no competing interests.

677

## 678 **Methods**

679

680 A key resource table (supplementary table 1) provides details about the reagents, strains, and  
681 software used in this study.

682

### 683 **Strains, media and chemicals**

684 The strains, plasmids and oligonucleotides used in this study are listed in Supplementary Table 1. The  
685 *E. coli* K-12 DH5 $\alpha$  strain was used for cloning procedures; *E. coli* K-12 BL21(DE3) strain was used  
686 for protein expression and purification; *E. coli* K-12 W3110 bearing the pUA66-*rrnB* vector (Kan<sup>R</sup>  
687 and GFP<sup>+</sup>, <sup>1</sup>) was used as recipient for antibacterial competition assays. Strains were routinely grown  
688 in lysogeny broth (LB) rich medium or in Sci-1-inducing medium (SIM; M9 minimal medium,  
689 glycerol 0.2%, vitamin B1 1  $\mu\text{g.mL}^{-1}$ , casaminoacids 100  $\text{mg.mL}^{-1}$ , LB 10%, supplemented or not with  
690 bactoagar 1.5%) <sup>2</sup> with shaking at 37°C. Plasmids were maintained by the addition of streptomycin  
691 (100  $\mu\text{g.mL}^{-1}$ ), kanamycin (50  $\mu\text{g.mL}^{-1}$ ), chloramphenicol (30  $\mu\text{g.mL}^{-1}$ ) or ampicillin (100  $\mu\text{g.mL}^{-1}$ ).  
692 Expression of genes from pCDF, pRSF and pETDuet vectors was induced with 1 mM of isopropyl- $\beta$ -  
693 D-thio-galactopyrannoside (IPTG, Eurobio) for 16h at 16 °C.

694

### 695 **Strains construction**

696 Gene deletion into the enteroaggregative *E. coli* 17-2 *tssK<sub>sfgfp</sub>* strain <sup>3</sup> was achieved by using a  
697 modified one-step inactivation procedure <sup>4</sup> as previously described <sup>5</sup> using plasmid pKOBEG <sup>6</sup>.

698 Briefly, a kanamycin cassette was amplified from plasmid pKD4 using oligonucleotide pairs carrying  
699 5' 50-nucleotide extensions homologous to regions adjacent to the gene to be deleted. After  
700 electroporation of 600 ng of column-purified PCR product, kanamycin-resistant clones were selected  
701 and verified by colony-PCR. The kanamycin cassette, inserted at the gene locus on the bacterial  
702 chromosome, was then excised using plasmid pCP20, leaving an FRT scar<sup>4</sup>. Gene deletions were  
703 confirmed by colony-PCR and sequencing. All the mutations have been previously trans-  
704 complemented for the T6SS-dependent bacterial competition or Hcp secretion phenotype by plasmid  
705 expressing the WT version of the T6SS genes TssFG<sup>7</sup> and TssK<sup>8</sup>.

706  
707

### 708 **Plasmid construction**

709 PCRs were performed using the Phusion DNA polymerase (Thermo Scientific). Restriction enzymes  
710 were purchased from New England Biolabs and used according to the manufacturer's instructions.  
711 Custom oligonucleotides were synthesized by Sigma Aldrich and are listed in Supplementary Table 1.  
712 Enteroaggregative *E. coli* 17-2 chromosomal DNA was used as a template for all PCRs. Construction  
713 of pCDF-TssK<sup>H</sup>-S<sup>F</sup>-G<sup>F</sup> has been previously described<sup>9</sup>. Plasmids pCDF-TssK<sup>H</sup>-S<sup>F</sup>-G<sup>F</sup>-E<sup>HA</sup> and  
714 pETDuet-VgrG<sup>HA</sup> were engineered by restriction cloning. Briefly, the sequences encoding the full-  
715 length *tssE* and *vgrG* were PCR-amplified using primers 5-pRSF-E<sup>HA</sup>  
716 (ATAAAGCTTAAGGAGATATACATATGCCGCGTCCTTCCCTTTATGAAATTCTCTATGGC)  
717 and 3-pRSF-E<sup>HA</sup>  
718 (ATAGCGGCCGCTCAAGCGTAATCTGGAACATCGTATGGGTACGTCTGCACGTAGCGCTGCT  
719 GTTTCAGATGGC), and 5-pETDuet-VgrG<sup>HA</sup>  
720 (ATAGGATCCAAGGAGATATACATATGAATCTCACTGACTCCCTGCAAATGTTTTATCCG  
721 G) and 3-pETDuet-VgrG<sup>HA</sup>  
722 (TATAAGCTTTCAAGCGTAATCTGGAACATCGTATGGGTATTCTGTTTCTCCATGAATTTTAC  
723 CTCCCAAATC), respectively. Primers introduced a C-terminal HA epitope tag extension  
724 (italicized in the primer sequences), and HindIII/NotI and BamHI/HindIII restriction sites (underlined  
725 in the primer sequences) respectively. All other plasmids were constructed by restriction-free cloning  
726<sup>10</sup>. Briefly, the gene of interest was amplified with oligonucleotides carrying 5' extensions annealing to  
727 the target vector. The product of the first PCR was then used as oligonucleotide for a second PCR  
728 using the target vector as template. All constructs have been verified by DNA sequencing (Eurofins  
729 Genomics).

730

### 731 **Interbacterial competition assay**

732 The antibacterial growth competition assay was performed as previously described<sup>11</sup>. Wild-type *E.*  
733 *coli* K-12 strain W3110 bearing the pUA66-*rrnB* plasmid (conferring kanamycin resistance and  
734 constitutive GFP fluorescence (*gfp* gene under the control of the ribosomal *rrnB* promoter,<sup>12</sup> was used  
735 as recipient. Attacker and recipient cells were grown for 16 h in LB medium, diluted in SIM to allow  
736 maximal expression of the *sci-1* gene cluster<sup>2</sup>. Once the culture reached  $A_{600nm} \sim 0.8$ , cells were  
737 harvested and normalized to  $A_{600nm} = 0.5$  in SIM. Attacker and recipient cells were mixed to a 4:1 ratio  
738 and 15- $\mu$ l drops of the mixture were spotted in triplicate onto a pre-warmed dry SIM agar plate  
739 supplemented or not with arabinose 0.5 mg.mL<sup>-1</sup>. After incubation for 4 h at 37°C, the bacterial spots  
740 were resuspended in LB and bacterial suspensions were normalized to  $A_{600nm} = 0.5$ . For the  
741 enumeration of viable prey cells, bacterial suspensions were serially diluted and spotted onto  
742 kanamycin LB plates. The assays were performed from at least three independent cultures, with  
743 technical triplicates and a representative technical triplicate is shown.

744

### 745 **TssKFGE complex production and purification**

746 The tags were rationally positioned at specific locations in the TssKFGE complex: Introduction of the  
747 tags (i) still permits protein-protein interaction as assayed by bacterial two hybrid (BTH) and (ii)  
748 allows trans-complementation of the T6SS-dependent "interbacterial competition" phenotype in a  
749 mutant deleted for a specific gene with a plasmid encoding a tagged version of this same gene. The  
750 pCDF-TssK<sup>H</sup>-S<sup>F</sup>-G<sup>F</sup>-E<sup>HA</sup> plasmid was transformed into the *E. coli* BL21(DE3) expression strain. Cells  
751 were grown at 37°C in lysogeny broth (LB) to  $A_{600nm} \sim 0.6$  and the expression of the *tssKFGE* genes

752 was induced with 1.0 mM IPTG for 16 h at 16 °C. Cell pellets were resuspended in ice-cold 50 mM  
753 Tris-HCl pH 8.0, 150 mM NaCl, 1 mM EDTA supplemented with DNase I (100 mg.mL<sup>-1</sup>), lysozyme  
754 (100 mg.mL<sup>-1</sup>), MgCl<sub>2</sub> (10mM) and EDTA-free protease inhibitor (Roche) to an *A*<sub>600nm</sub> of 125. Cells  
755 were broken using an Emulsiflex-C5 (Avestin) and clarified by ultracentrifugation at 20,000×g for 30  
756 min. The supernatant was loaded onto a 5-mL HisTrap HP (GE Healthcare) column equilibrated in  
757 affinity buffer (50 mM Tris-HCl pH 8.0, 150 mM NaCl) supplemented with 20 mM imidazole. The  
758 column was then washed using the affinity buffer supplemented with 50 mM imidazole and the  
759 TssKFG complex was eluted in the same buffer supplemented with 250 mM imidazole. Peak  
760 fractions were pooled and loaded onto a Superose 6 10/300 column (GE Healthcare) equilibrated in 50  
761 mM HEPES pH 7.5, 150 mM NaCl. The complex eluted as a single monodisperse peak and the  
762 sample was used for EM sample preparation.

### 763

### 764 **Protein production and purification for interaction studies**

765 Plasmids expressing the genes combination of interest were co-transformed into *E. coli* BL21(DE3)  
766 and cells were treated as described before. For His-tag affinity, the supernatant was loaded, washed  
767 and eluted as above. For strep-tag affinity, the supernatant was loaded onto a 5-mL StrepTrap HP  
768 column (GE Healthcare), washed with affinity buffer and eluted in affinity buffer supplemented with  
769 2.5 mM desthiobiotin (IBA Technologies). The lysate, flow through, wash and elution fractions were  
770 collected, resuspended in Laemmli loading buffer supplemented with 300 mM 2-Mercaptoethanol,  
771 heated for 10 min at 96°C prior to analyses by SDS-PAGE and immunoblotting.

### 772

### 773 **SDS-PAGE, protein transfer, immunostaining and antibodies**

774 SDS-PAGE was performed on Bio-Rad Mini-PROTEAN<sup>®</sup> systems using standard protocols. For  
775 immunostaining, proteins were transferred onto 0.2-µm nitrocellulose membranes (Amersham  
776 Protran). Immunoblots were probed with primary antibodies and goat secondary antibodies coupled to  
777 alkaline phosphatase, and developed in alkaline buffer in presence of 5-bromo-4-chloro-3-  
778 indolyphosphate and nitro-blue tetrazolium. The anti-HA (HA-7 clone, Sigma Aldrich), anti-Flag  
779 (M2 clone, Sigma Aldrich), anti-StrepII (Sigma Aldrich), anti VSV-G (Sigma Aldrich) and anti-5His  
780 (Sigma Aldrich) monoclonal antibodies, and mouse secondary antibodies (Millipore) were purchased  
781 as indicated.

### 782

### 783 **Native polyacrylamide gel electrophoresis**

784 After overnight cultures in LB, the enteroaggregative *E. coli* EAEC strain 17-2-*tssK<sub>sfgfp</sub>* and its mutant  
785 variants were diluted 1/100 in 500 mL of SIM and grown at 37°C to an *A*<sub>600nm</sub> ~ 1,2. Cells were  
786 harvested, resuspended in ice-cold 50 mM Tris-HCl pH 8.0, 150 mM NaCl, 1 mM EDTA to an *A*<sub>600nm</sub>  
787 = 120 and broken using an Emulsiflex-C5 (Avestin). After clarification by ultracentrifugation at  
788 20,000×g for 30 min, lysates were loaded on a native 4-16% gel (Mini-PROTEAN<sup>®</sup> TGX, Bio-Rad).  
789 After migration, proteins and protein complexes were transferred onto a nitrocellulose membrane and  
790 immunoblotted as described above.

### 791

### 792 **Mass spectrometry**

793 Purified TssKFG and TssKFG complex were first buffer exchanged with 500 mM  
794 ammonium acetate by size exclusion chromatography on Superdex 200 increase (3.2 / 300) using a  
795 ÄKTAmicro System (GE healthcare) at isocratic flow of 50 µL.min<sup>-1</sup>. Samples were then nano-  
796 electrosprayed using a TriVersa NanoMate (Advion Biosciences, Ithaca, USA) coupled to a Synapt  
797 G2-Si mass spectrometer (Waters Corporation, Manchester, UK). The instrument was calibrated from  
798 1,000 m/z to 12,000 m/z with CsI (50 mg/mL<sup>-1</sup>) with an accuracy of 6 ppm. Native mass  
799 measurements were recorded between 2,000 and 20,000 m/z with sensitivity mode activated. The  
800 following settings were chosen: sampling cone 150 V, source offset 45 V, source temperature 40°C,  
801 trap gas flow 5 mL.min<sup>-1</sup>, helium cell gas flow 180 mL.min<sup>-1</sup>. Sub-complexes were obtained with the  
802 same parameters and additional collisional activation up to 60 NCE (Normalized Collisional Energy).  
803 Data were accumulated several minutes, averaged and smoothed with the Mass Lynx smoothing  
804 Algorithm (30 cycles, 30 amu large channel). Theoretical masses were calculated with the algorithm  
805 embedded within MassLynx using the protein sequence of the constructs. Measured masses were

806 obtained averaging the mass calculated for the most intense charge states of the complex with a  
807 minimum of 3 charge states.

808

### 809 **Fluorescence microscopy, image treatment and analyses**

810 Fluorescence microscopy experiments were performed as described<sup>8,13</sup>. Briefly, cells were grown  
811 overnight in LB medium and diluted to  $A_{600nm} \sim 0.04$  in SIM. Exponentially growing cells ( $A_{600nm} \sim$   
812  $0.8-1$ ) were harvested, washed in phosphate-buffered saline buffer (PBS), resuspended in PBS to  
813  $A_{600nm} \sim 50$ , spotted on a 1.5% agarose pad and covered with a cover slip. For domain interference, the  
814 *E. coli* 17-2 *tssK-sfgfp* or *tssB-mCherry* strains expressing TssK or TssG domains were cultured as  
815 described above, except that 0.05% (w/v) arabinose was added in the culture once reached  $A_{600nm} \sim 0.6$   
816 for 30 min. Fluorescence and phase contrast micrographs were captured using AxioImager M2  
817 microscope (Zeiss) equipped with an OrcaR2 digital camera (Hamamatsu). Fluorescence images were  
818 acquired with a minimal exposure time to reduce bleaching and phototoxicity effects, typically 500 ms  
819 for TssK-sfGFP and 200 ms for TssB-mCherry. Noise and background were reduced using the  
820 'Subtract Background' (20 pixels Rolling Ball) and Band plugins of imageJ (Image J, National  
821 Institutes of Health). The sfGFP foci were automatically detected using the microbeJ plugin  
822 (<http://www.microbej.com/index.html>). Box plots representing the number of detected foci for each  
823 strain were made using microbeJ. The number of sheath per cells was measured manually. Microscopy  
824 analyses were performed at least three times, each in technical triplicate, and a representative  
825 experiment is shown.

826

### 827 **Cryo-EM grids preparation and data acquisition**

828 For cryo-EM analyses, the buffer of the purified TssKFGE complex was exchanged for 50 mM  
829 HEPES pH 7.5, 150 mM NaCl to a final protein concentration of  $0.2 \text{ mg}\cdot\text{mL}^{-1}$ .  $3.5 \mu\text{L}$  of the protein  
830 solution was deposited on Lacey grids and vitrified using a Vitrobot (Thermo Fisher, Waltham, MA,  
831 USA) (parameters: blotting 4 s, temperature  $4^\circ\text{C}$ , humidity 100 %). Micrographs (Supplementary Fig.  
832 11a) were recorded at a specimen temperature of 85 K in a Titan Krios electron microscope (Thermo  
833 Fisher, Waltham, MA, USA) at 300 kV and a nominal magnification of 130,000 on a K2 summit  
834 direct electron detector mounted on a Bioquantum LS/967 energy filter (Gatan, Pleasanton, California)  
835 in counting mode with a pixel size of  $1.1 \text{ \AA}$ , at an electron flux of about  $12.35 \text{ e-}/\text{px}\cdot\text{s}$ . Dose-  
836 fractionated movie frames (30 in total) were acquired for 4 s with 0.13 s exposure time per frame. The  
837 total electron dose was  $\sim 45 \text{ e-}/\text{\AA}^2$  ( $1.5 \text{ e-}/\text{\AA}^2/\text{frame}$ ). The defocus range chosen for the automatic  
838 collect was 0.7 to  $2 \mu\text{m}$ , which resulted in an actual range between 0.4 to  $3 \mu\text{m}$ .

839

### 840 **Cryo-EM image processing**

841 750 micrographs were processed (Supplementary Fig. 10a). Subframes were divided into  $5 \times 5$  patches  
842 and corrected with MotionCor2, with dose weighting ( $1.5 \text{ e-}/\text{\AA}^2/\text{frame}$ ) to dampen the high-resolution  
843 signal in later frames<sup>14</sup>. CTF parameters were estimated by gCTF<sup>15</sup>. Particles on micrographs were  
844 picked manually in box size of 450 pixels and classified into 2D class averages. Selected classes were  
845 used as references for autopicking in RELION 2.1<sup>16</sup>. The total number of initial extracted particles  
846 (167,825) was reduced to 52,069 by subsequent rounds of 2D classifications (Supplementary Fig. 10b)  
847 and an initial model (Supplementary Fig. 10c) of what appears to be 2 TssKFGE full complexes  
848 ( $12 \times \text{TssK}$ ,  $4 \times \text{TssF}$ ,  $2 \times \text{TssG}$ ,  $2 \times \text{TssE}$ ) was generated on cryoSPARC 0.6<sup>17</sup>. The selected particles  
849 from the 2D classifications were converted back to RELION 2.1 using the script *csparc2star.py*<sup>18</sup> and  
850 then subjected to an additional round of 2D and 3D classification (Supplementary Fig. 10c), with the  
851 initial model low-pass filtered to  $60 \text{ \AA}$ . A final cleaner dataset of 32,504 particles was selected for  
852 further processing. The  $40 \text{-\AA}$  low-pass filtered 3D class was then used as an initial model for 3D  
853 refinement with a solvent mask corresponding to most well defined half of the larger TssKFGE  
854 complex ( $6 \times \text{TssK}$ ,  $2 \times \text{TssF}$ ,  $1 \times \text{TssG}$ ,  $1 \times \text{TssE}$ ). No symmetry was applied during any of the 3D  
855 classifications and refinements. To obtain the density map of the single repeating unit of the assembly  
856 of the two complexes (hereafter called TssKFGE), the complex with the least defined wing was  
857 subtracted, and a soft mask was applied to the remaining region for 3D auto-refinement. The final  
858 resolution was  $4.6 \text{ \AA}$ , calculated with masked post-process by refining two half-maps independently,

859 according to the “gold standard” FSC 0.143 criterion. The B factor applied of -136 gave a local  
860 resolution range between 3.9 and 18 Å (Supplementary Fig. 11a-c).

861 To obtain the best density map for the root-like domains that correspond to TssK, the regions  
862 corresponding to the wings were subtracted and a soft mask was applied to the TssK trimers during  
863 autorefinement, producing a map with a 4.3-Å overall resolution. The calculated B factor was -111  
864 and it gave a local map resolution of 3.8-33 Å (Supplementary Fig. 11d-f, j-k).

865 Masking was not sufficient to improve the density map of the flexible regions. A re-centering of the  
866 particles in the wings region was thus performed using the REP algorithm<sup>19</sup> and the box size was  
867 reduced to 200 pixels. A masked 3D auto-refinement to exclude the root-like domains was performed  
868 to obtain a resolution of 4.7 Å (4.3-8 Å local with B factor of -202; Supplementary Fig. 11g-i).

869 All of the densities obtained were subjected to Autosharpen<sup>20</sup> in the Phenix software package. All the  
870 models were built on autosharpened densities. Subsequent molecular graphics and analyses were  
871 performed using UCSF Chimera<sup>21</sup>.

872

### 873 **Evolutionary Covariance Analysis.**

874 Residue–residue contacts can be predicted based on sequence information alone through the  
875 evolutionary covariance analysis<sup>22</sup> Essentially, the prediction of residue–residue contacts is linked to  
876 strong evolutionary constraints, such as the presence of functionally important structures, and is  
877 measured by the covariance of contacting residues. Evolutionary constraints can be detected at a  
878 sequence level by aligning thousands of homologous protein sequences. Statistical probability models  
879 can separate direct from indirect residue–residue couplings, increasing the signal-to-noise ratio in the  
880 predicted contact map. Therefore, contacts with the strongest signal, indicated by the highest global  
881 statistical scores, are most likely to represent the true residue interactions in a protein. In this work we  
882 use two software packages that uses distinct statistical probability models: EVcomplex<sup>23</sup> and RaptorX  
883<sup>24</sup> for inter-molecular and intra-molecular contact prediction, respectively. EVcomplex computes co-  
884 evolution between proteins, pairing up protein sequences and assuming proximity of the two  
885 interacting partners on the genome, with the goal of reducing incorrect pairings. The paired sequences  
886 are concatenated and statistical co-evolution analysis is performed using EVcoupling<sup>25</sup>. The RaptorX  
887 algorithm predicts intra-molecular contacts by integrating evolutionary coupling, pairwise potentials,  
888 and sequence conservation information through an ultra-deep neural network.

889

890

### 891 **TssKFGE model fitting and de novo tracing**

892 Two copies of the trimeric TssK unit (PDB: 5M30;<sup>9</sup> were docked into the EM density map of the  
893 TssKFGE complex and fit as rigid bodies in Chimera<sup>21</sup>. Missing regions were manually built using  
894 Coot<sup>26</sup>. The final model was refined by multiple rounds of manual refinement in Coot<sup>26</sup>, Rosetta  
895 refine<sup>27</sup> and the real-space refine function of Phenix<sup>28</sup>.

896 Owing to the lack of structural information for TssF and TssG and the limited resolution of the density  
897 map in that region, we devised an iterative semi-automatic protocol that employed several sources of  
898 information and pieces of software (Supplementary Fig. 12). The sources of information included the  
899 EM density map, the stoichiometry and the symmetry of the TssFG subcomplex, the position of bulky  
900 residues in the sequence, a homology model of TssF based on the T4 bacteriophage gp6 (generated  
901 using i-TASSER, consensus secondary structure obtained using PSIPRED<sup>29</sup>, Rosetta<sup>27</sup>, Phyre2<sup>30</sup>,  
902 DeepCNF<sup>25</sup>, and i-TASSER<sup>31</sup>, and intra-molecular contact predictions for TssF and TssG using the  
903 RaptorX contact prediction tool<sup>31</sup> (Supplementary Fig. 12b). Contact maps are binary two-  
904 dimensional matrices that represent the proximity between all residue pairs for a given protein<sup>27</sup>. The  
905 RaptorX algorithm predicts contacts by integrating evolutionary coupling, pairwise potentials, and  
906 sequence conservation information through an ultra-deep neural network. Predicted contact maps were  
907 obtained by filtering RaptorX contacts with a score higher than 0.4. Model contact maps, which are  
908 compared with the predicted ones, were obtained from a structure calculating the pairwise distances  
909 between C $\alpha$  atoms and considering as a contact any distance below 12 Å. We tested the quality the  
910 predicted contact maps by calculating the accuracy on a known structure. Using the enteroaggregative  
911 *E. coli* TssK structure as model<sup>9</sup>; PDB: 5M30) (Supplementary Fig. 12c), the ratio between predicted  
912 contacts consistent with the structure and the total contacts within the structure gave an accuracy of  
913 0.97 (Supplementary Table S3).

914 The protocol described below iterates between structural refinement and sequence-structure  
915 registration based on contact prediction. It is organized into four steps (Supplementary Fig. 12a):  
916 *Step 1. Initial segmentation and manual tracing.* The TssFG map was segmented using Segger v1.9.4  
917 in UCSF Chimera <sup>21</sup> and the density of one half of the wing superimposed with the other half to  
918 identify repeating patterns due to the presence of two TssF monomers in the complex. The segmented  
919 map identified densities corresponding to TssG and the two TssF subunits. An initial C $\alpha$  tracing of the  
920 TssFG complex was based on the three density segments. The sequence registering was guided by  
921 sequence position of bulky amino-acids and consensus prediction of secondary structures. The model  
922 building was aided by the use of the Coot-trimmings script <sup>32</sup> and sharpening of the map was  
923 modulated by varying the resolution limit.

924 *Step 2. Sequence Registration using predicted contact maps.* The model was validated and registered  
925 using residue contact prediction <sup>33</sup>. The contact map of the obtained model was computed and aligned  
926 to the predicted contact-map using the MapAlign software <sup>34</sup>. Using the resulting contact-map  
927 alignment we identified regions of the model that agree and disagree with the predicted contact-map.  
928 The boundaries of these regions were used to divide the structure into several fragments. The  
929 connectivity and the sense (N- to C-terminus orientation) of the fragments were globally optimized  
930 using dynamic programming and the MapAlign scoring function.

931 *Step 3. De novo modeling of inconsistent regions.* The model generated in the previous step was again  
932 validated comparing its contact-map with the predicted contact-map. Regions in disagreement (TssG-  
933 D1, residues 1-144; TssG-D2 body, residues 180-300; and TssF-D1, residues 495-585) were modeled  
934 de novo using ARIA with predicted contacts as distance restraints <sup>35</sup>. Inter-residue contacts for the  
935 TssG-D1, TssG-D2 and TssF-D1 domains were predicted from co-evolution analysis using RaptorX <sup>31</sup>  
936 and the top scoring contacts were converted to distance restraints. Secondary structure predictions  
937 from DeepCNF <sup>25,36</sup> were converted to canonical dihedral angle restraints for residues predicted to be  
938 in  $\alpha$ -helical and  $\beta$ -strand conformation. Additionally, hydrogen bond restraints were generated  
939 between residues  $i$  and  $i+4$  in regions predicted as  $\alpha$ -helical (same face of the helix). Atomic models  
940 were calculated by successive rounds of restrained molecular dynamics simulated annealing with CNS  
941 <sup>37</sup> using the iterative ARIA approach <sup>35,38</sup>. At each iteration, 100 conformations were produced using  
942 inter-residue distance, dihedral angle and hydrogen bond restraints and clustered from the coordinates  
943 of C $\alpha$  atoms. The 15 best conformations of the lowest-energy cluster were then used to refine the list  
944 of predicted contacts on the basis of their structural consistency. A conformational database potential  
945 term was also used in the energy function during simulated annealing <sup>39</sup>.

946 *Step 4. Refinement.* All the models of different domains independently generated in step 2 and 3 were  
947 merged together in a single chain. The coordinates of the obtained single-chain model were modified  
948 manually using Coot <sup>26</sup> and refined with repeated rounds of Coot, Rosetta refine <sup>40</sup> and the Phenix real-  
949 space refine function <sup>28</sup>. Steps 2-4 were repeated until a model maximally consistent with the EM map  
950 (Supplementary Fig 12e) and the predicted contact-maps was obtained.

951 For TssK and TssFGE the EMRinger <sup>41</sup> scores were 1.74 and 0.23 and the Molprobit <sup>42</sup> scores were  
952 1.9 and 2.36 respectively. Final accuracies of the TssF and TssG contact maps generated from the  
953 structures were 0.85 and 0.87, respectively (Supplementary Table 2). The models built in TssK and  
954 TssFGE were then fit as rigid bodies in the TssKFGE structure with EMRinger and Molprobit scores  
955 of 1.62 and 1.94 respectively (Supplementary Table 2).

956 FSC curves were calculated between the model and the map using Phenix after real space refinement.  
957 To assess the presence of overfitting, as described before <sup>43</sup>, the FSC computed between the model and  
958 the autosharpened map (FSC-sum) was compared to the FSC calculated between the "shaken" model  
959 (applying a random perturbation of 0.5Å to the atomic coordinates, with the module pdbtools of  
960 Phenix, Adams et al., 2010) refined against the first half map (FSC-work) and the resulting model  
961 refined with the second half map (FSC-free, Supplementary Figure 11c,f,i). The overlapping between  
962 the FSC-free and FSC-work curves demonstrates the absence of overfitting. Interaction surfaces were  
963 analysed using the PISA software <sup>45</sup>. For illustration purposes, TssFGE secondary structures were  
964 predicted using Cablam <sup>46</sup>.

965

966 **Data and software availability**

967 The cryo-EM structure of the full complex TssKFG , TssK and TssFGE have been deposited in the  
968 EMDDB under ID codes EMD-0008, 0010, 0009. The TssKFG, TssK and TssFGE model have been  
969 deposited in the PDB under ID codes PDB 6GIY, 6GJ3, 6GJ1. Raw cryo-EM data are available on  
970 request.

## Supplementary Results

### *Native mass spectrometry.*

Native mass spectrometry (Native MS) was used to measure the mass of the intact protein complex from which the stoichiometry can be deduced<sup>1</sup>. The molecular mass of each individual subunit was firstly checked in denaturing conditions. A molecular mass of  $499,490 \pm 200$  Da was obtained for the complex indicating that the TssKFGE complex comprises six TssK, two TssF, one TssG and one TssE subunits (TssK<sub>6</sub>F<sub>2</sub>G<sub>1</sub>E<sub>1</sub>; theoretical mass: 498,905 Da) (**Supplementary Fig. 3b**). The difference from the measured and theoretical masses arises from the presence of numerous salt adducts, which is a common phenomenon in native MS. A similar stoichiometry was obtained for the purified TssKFG complex (TssK<sub>6</sub>F<sub>2</sub>G<sub>1</sub>; measured mass:  $481,916 \text{ Da} \pm 200 \text{ Da}$ , theoretical mass: 481,520 Da; **Supplementary Fig. 3c**). For TssF, TssG and TssE, this stoichiometry is in agreement with previous studies, indicating the conserved nature of the T6SS wedge among various species. Interestingly, native MS analyses confirmed the peripheral and weaker association of TssE in the TssKFGE complex, as TssE dissociates first when the TssKFGE complex is submitted to collisional activation (**Supplementary Fig. 3d**). Only 3 TssK monomers per wedge complex were found in *Serratia marcescens* and uropathogenic *E. coli*<sup>2-4</sup>. These discrepancies could be explained by the different approaches used to purify or assess the stoichiometry of the complex, or by differences in T6SS baseplate composition in these various bacterial species.

### **Segmentation of the CryoEM map**

Our native MS and biochemical analyses of the purified TssKFGE complex unambiguously showed that TssE is present with a stoichiometry of one TssE per complex. At lower density thresholds, the cryo-EM map reveals a density that could be attributed to TssE at the tip of the TssFG. In agreement with this hypothesis, a model of the EAEC TssE generated based on the gp25 crystal structure (PDB: 5IW9;<sup>2</sup>) fits into the identified density (**Fig. 2h**).

### ***Dominant-negative approach by “small domain interference” (SDI)***

First, to validate this approach, we performed SDI with TssK sub-domains. It was previously shown that the TssK N-terminal shoulder domain is anchored into the baseplate whereas the TssK C-terminal head domain binds the membrane complex<sup>5</sup>. We reasoned that overproduction of TssK shoulder (TssK<sub>S</sub>) or TssK shoulder and neck (TssK<sub>SN</sub>) sub-domains should interfere with T6SS wedges assembly, and by lacking the head domain will prevent proper association with the membrane complex. *In vivo*, overproduction of TssK<sub>SN</sub> and, to a lower extent, TssK<sub>S</sub> in wild-type cells impacts the assembly of T6SS wedges, blocks T6SS sheath dynamic and prevents T6SS activity (**Supplementary Fig. 5a-c**). The difference in the negative effect observed between TssK<sub>SN</sub> and TssK<sub>S</sub> could be explained by the stabilization of the TssK trimer by the helix packing of the neck domains<sup>5</sup> that results in a better incorporation of TssK<sub>SN</sub> compared to TssK<sub>S</sub> into the TssKFGE complex *in vitro* (**Supplementary Fig. 5d**). We then hypothesized that overproduction of the TssG domain which mediates the recruitment of TssK, should have a dramatic negative effect on T6SS function. Our competition experiments showed that only the overproduction of TssG-D2 has a negative effect on the T6SS-dependent killing of *E. coli* target cells (**Supplementary Fig. 5e**). This result confirms that TssG-D2 has a central role for T6SS wedge assembly. To provide further evidence for the position of TssG-D2 at the interface between TssF and the two TssK trimers, we used the EVcomplex program (Hopf et al., 2014) to predict inter-molecular interactions between TssG and TssK using evolutionary covariance analysis (see Methods section). First, the algorithm confirmed our previous findings, showing that the TssG-D2 domain is the major interface with the TssK shoulder domain. Second, the algorithm predicted a number of potential TssK<sub>S</sub>-TssG-D2 interfacial residue pairs with high scores (**Supplementary Fig. 6a**). The corresponding TssG-D2 residues, Pro-240 and Leu-255 were substituted, and these TssG-D2 variants (P240A and L255A and P240A-L255A) were assayed by SDI in interbacterial competition experiments. Although these TssG-D2 variants were produced at levels comparable to the wild-type TssG-D2 (see insets in **Supplementary Fig. 6b**), the TssG-D2 P240A and L255A mutants were drastically affected in their ability to inhibit T6SS-function. Combining the P240A and L255A mutations decreases even further the T6SS-inhibitory effect of TssG-D2 overproduction (**Supplementary Fig. 6b**).

### ***The TssK-TssFG interface***

To rationalize the results of the Alanine mutation analysis discussed above, we mapped the positions of TssG Pro-240 and TssG Leu-255 on the TssKFG structure. Only Pro-240 is proximal to the TssKG interface, being directly in contact to TssK Leu-14. Thus, its mutation is compatible with a TssKG interface destabilization. On the other hand, TssG Leu-255 is far from the interface, and its mutation probably destabilized the fold of the C-terminal region. When compared with the structure, the Alanine mutational study above has revealed some key residues important for the stability of the TssK-G interaction stability, although the molecular mechanism remains to be addressed.

## **Supplementary Discussion**

### ***The T6SS baseplate - membrane complex connection***

As mentioned in recent publications, there is a symmetry mismatch between the 5-fold symmetric TssJLM membrane complex and the 6-fold symmetric baseplate<sup>4-6</sup>. In this configuration, the 36 copies of TssK (6 per individual wedge) could contact the 10 copies of TssLM. However, our cryo-EM structure shows that the TssK<sub>H</sub> domains within each TssK trimer are in different orientations. We thus suggest that the flexibility of the TssK<sub>H</sub> domains is key to adapt to the symmetry mismatch and that only a subset of these TssK<sub>H</sub> domains engages with the membrane complex. This symmetry mismatch is likely to be important for T6SS function. It may maintain the system under a metastable conformation, allowing a higher turnover rate of ejection of the Hcp tube. It may also accommodate the large conformational changes expected between the baseplate and the membrane complex during sheath contraction. Finally, it may play a critical role in the controlled dissociation of the baseplate after firing, as suggested for the dissociation of V-ATPases<sup>7</sup>.

### ***Comparison between T6SS and bacteriophage baseplates.***

*Analogy between the T6SS baseplate and the “simple contractile baseplate” from the Mu phage* – The architecture and stability of the TssKFG wedge complex is reminiscent to the Mu phage baseplate wedge<sup>8</sup>. Although sequence identity between the T6SS and Mu phage protein is very low, their respective overall structural organization suggests that the T6SS and Mu phage wedge complexes are highly similar. The Mu phage wedge is formed by the proteins Mup46, Mup47, and Mup48. Mup46 is a gp25 homolog, like TssE. Mup47 is homologous to the gpJ wedge protein of *E. coli* phage P2, like TssF<sup>9</sup>. Mup48 is homologous to the gpI wedge protein of *E. coli* phage P2, like TssG<sup>9</sup>. Mup47 and Mup48 form a stable complex, a behavior comparable with the T6SS TssF-TssG complex<sup>9</sup>. However, the relative stoichiometry of both wedge complexes differs significantly: 2:2:2 for Mup46/47/48 and 6/2/1/1 for TssK/F/G/E. The whole Mu phage baseplate is formed by the attachment of dimers of the Mup46/47/48 wedge (BW1, BW2 and BW3, according to the standard nomenclature previously proposed<sup>8</sup>) on the Mup43/44 hub complex (BH1 and BH2). However, the predicted T6SS baseplate does not seem to contain such BH1/BH2 hub complex. The T6SS proteins share many structural characteristics with “simple” contractile baseplates, even though TssK has no equivalent in Mu phage proteins. We have previously demonstrated that TssK is homologous to lactococcal siphophage receptor binding proteins (RBP) proteins<sup>5</sup> and we have shown in this work that TssF and TssG are partly a T4 phage gp6 and gp7 homologs. Therefore, the T6SS wedge complex and baseplate seem to be an evolutionary “patchwork”, rooted in T4 bacteriophage, siphophage and Mu phage.

*TssF and TssG are gp6 and gp7 counterparts in the T4 phage baseplate* – Previous structural studies on the T4 bacteriophage have reported the moderate to high-resolution structures of the whole baseplate<sup>2,10-12</sup>. Despite no sequence conservation, it was proposed that TssF and TssG could be the structural counterparts of gp6 and gp7 respectively<sup>2,9</sup>. Gp6 and gp7 are subunits of the T4 phage inner baseplate in which they interact tightly to form the T4 phage wedge complex. The TssG and gp7 structures are not readily superimposable. However, TssG and the central part of gp7 (residues 640-900) display the same domain organization with an N-terminal antenna followed by a helical neck domain and an  $\alpha/\beta$  body (**Supplementary Fig. 9a**). The rest of the gp7 structure is specific to the T4 baseplate. By contrast, based on secondary structure predictions<sup>9</sup>, TssF shares much higher structural homology with the N-terminal region of gp6 (**Supplementary Fig. 9b**). The domain from residue 1 to 410 of gp6 is composed of an N-terminal antenna followed by two consecutive  $\beta$ -sandwich domains (called the wing domains) and an  $\alpha/\beta$  domain (called the trifurcation domain). These domains resemble the TssF antenna, D2, BD and D4

domains, respectively (**Supplementary Fig. 9b**). The C-terminal region of gp6 structure is not present in TssF and is not found in any protein of the T6SS baseplate. Strikingly, not only TssF and TssG adopt a similar structure to portions of gp6 and gp7, but the structural organization of the T4 (gp6)<sub>2</sub>-gp7 heterotrimeric unit is conserved in the T6SS wedge complex (**Fig. 5a-b**). In the T4 baseplate, the backbone of the wedge domain is made of a heterotrimeric helical bundle and a trifurcation unit, which are made of the gp6/gp7 antennas and of the gp6/gp7  $\alpha/\beta$  domains, respectively. This trimeric scaffold, which tightly connects gp7 and the two gp6, is very similar to that of the TssFG complex (**Fig. 5a-b**). Although the organization is identical, it is interesting to note that the T4 phage trifurcation unit comprises three equivalent domains made of two helices and one three-strands  $\beta$  sheet while the TssFG trimeric scaffold contains two helices and one four-strands  $\beta$  sheet (**Fig. 5a-b**).

*Inter-wedge contacts are different in the T4 and T6SS baseplates* – The multimerization of T6SS wedges into the hexagonal baseplate diverge from the bacteriophage counterpart. In the T6SS baseplate, we showed that the inter-wedge contacts are mostly mediated by TssFa-TssFb interactions that spread in different domains of both protomers (**Fig. 4b**). In the T4 baseplate, the inter-wedge contacts are also mediated by gp6a/gp6b interactions. However, these interactions are restricted to the dimerization of a T4-specific gp6 C-terminal domain (residues 412-659) (**Fig. 5c**). Within each T4 wedge complex, these C-terminal domains are directly connected to the trifurcation unit. Therefore, a continuous ring of alternating trifurcation units and dimers of gp6 C-terminal domains stabilize the T4 inner baseplate<sup>2,12,13</sup>. The T4 phage baseplate also comprises an additional subunit, absent from the T6SS baseplate, gp8, that interacts with the N- and C- terminal domains of gp7 and thus reinforces the overall structure.

*Interaction of the T4 and T6SS baseplates with the spike* – Both T4 and T6SS baseplates contain a constriction at the center of the wedge ring that is delineated by gp6b and TssFa respectively. In the T6SS baseplate, TssFa wing domains exclusively cover the cavity that receives the VgrG gp27-like hub domain (**Fig. 5c-d**, **Supplementary Fig. 9c**). In the T4 baseplate, the gp6a wing domain mostly contributes to the central constriction but the gp27 hub position is stabilized in the cavity by a T4-specific component, gp53 (**Fig. 5c**, **Supplementary Fig. 9c**).

*Interaction of the T4 and T6SS baseplates with the contractile sheath* – The structure of the sheath component of the T4 phage gp18 is known (PDB: 3FOH; <sup>14</sup>). Based on the cryo-EM structure of the native T4 phage tail in the extended conformation (EMD-1126; <sup>15</sup>) determined at 12 Å, it is possible to fit gp18 in the sheath density and to reconstitute the extended sheath structure. The contacts between the sheath and the baseplate subunits can be inferred after docking to the T4 phage baseplate structure<sup>2</sup>. These contacts are in agreement with previously published biochemical and genetics data<sup>12,16,17</sup>. Overall the structures of the T4 and T6SS sheath building blocks (gp18 and TssBC complex respectively) are different (**Supplementary Fig. 9d-e**). However, they can be split in similar domains: an N-terminal antenna domain, a central globular domain and an  $\alpha/\beta$  domain that protrudes from the central domain (**Supplementary Fig. 9d-e**). Strikingly, TssE and gp25 interact similarly with the sheath  $\alpha/\beta$  domain and share the same fold as these TssBC and gp18 domains (**Supplementary Fig. 9d-e**). The baseplate-sheath connections in phage T4 and T6SS have conserved features but are stabilized by specific contacts. The N-terminal domains of gp18 and of TssBC interact with one of the wing domains of gp6b or TssFb respectively (**Supplementary Fig. 9d-e**). In the T4 phage, the central domain of gp18 interacts with a T4-specific protein, gp53 (**Supplementary Fig. 9e**). In the T6SS, this interaction is replaced by the interaction with the N-terminal head domain of TssG, which is T6SS-specific (**Supplementary Fig. 9d**).

*Specialization of the apical part of the T4 and T6SS baseplates* – The T4 phage and the T6SS baseplates are specialized molecular machines that interact with different targets. The T4 phage baseplate interacts with the bacterial surface prior to infection, while the T6SS baseplate interacts with the T6SS membrane complex. To achieve this specialization, the T4 and T6SS baseplates contain dedicated adaptor proteins recruited by gp7 and its TssG counterpart (**Fig. 5c**). In T4, the N- and C- terminal domains of gp7 interact with gp9 and gp10, which in turn assemble the short tail fiber proteins gp12 (**Fig. 5c-f**)<sup>17-20</sup>. In T6SS, the TssG foot domains recruit two TssK trimers, which then interact with the T6SS membrane complex to anchor the T6SS contractile device to the bacterial cell envelope (**Fig. 5c-f**).

*Assembly mechanism and stability of the T4 and T6SS baseplates* – In the T4 bacteriophage the wedge complex appears to be transient or less stable preventing its purification. By contrast, the T6SS wedge complex is much more stable and prone to purification, as shown by the isolation of TssKFG or TssKFGGE complexes in EAEC, *S. marcescens* and uropathogenic *E. coli* (this work; <sup>2,3</sup>) This higher stability of a preformed T6SS baseplate intermediate may reflect an adaptation to the secretion process. One hypothesis is that a subset of toxin effectors needs to be loaded onto VgrG <sup>21-23</sup>, hence delaying the polymerization of the wedge around the VgrG hub. By contrast, the fully assembled T4 phage baseplate is much more stable than the T6SS baseplate, since we did not succeed to purify the T6SS hexagonal baseplate. At the molecular level, TssF-TssF inter-domain interactions appear to be less tightly connected in the fully assembled T6SS baseplate, involving a limited contact surface area, as compared to bacteriophage T4 gp6-gp6 contacts. Consequently, the connection between individual T6SS wedges seems to be weaker, in agreement with the lower stability of the T6SS baseplate compared to that of bacteriophage T4. In addition, this could be explained by the presence of the T4-specific gp53 subunit that has been shown to promote polymerization of the wedges to form a hubless baseplate <sup>19</sup>. This difference may have functional implications. In phage T4, the hubless baseplate needs to remain stably associated during the transport of the phage genome. By contrast, after firing, the T6SS baseplate needs to dissociate, releasing individual wedges that will presumably assemble a new baseplate at the membrane complex. This reversible association would allow a recycling of the individual T6SS wedges.

**Supplementary Figure 1. Statistical analysis of TssK<sub>sfGFP</sub> foci formation. Related to Figure 1.**

Statistical analysis of TssK<sub>sfGFP</sub> foci formation in various T6SS mutant backgrounds. Shown are the box-and-whisker plots of the measured number of TssK<sub>sfGFP</sub> foci per cell for each indicated strain with the lower and upper boundaries of the boxes corresponding to the 25th and 75th percentiles respectively (black dot, the median values for each strain; whiskers, the 10th and 90th percentiles); The number of cells analyzed for each strain is indicated on top.

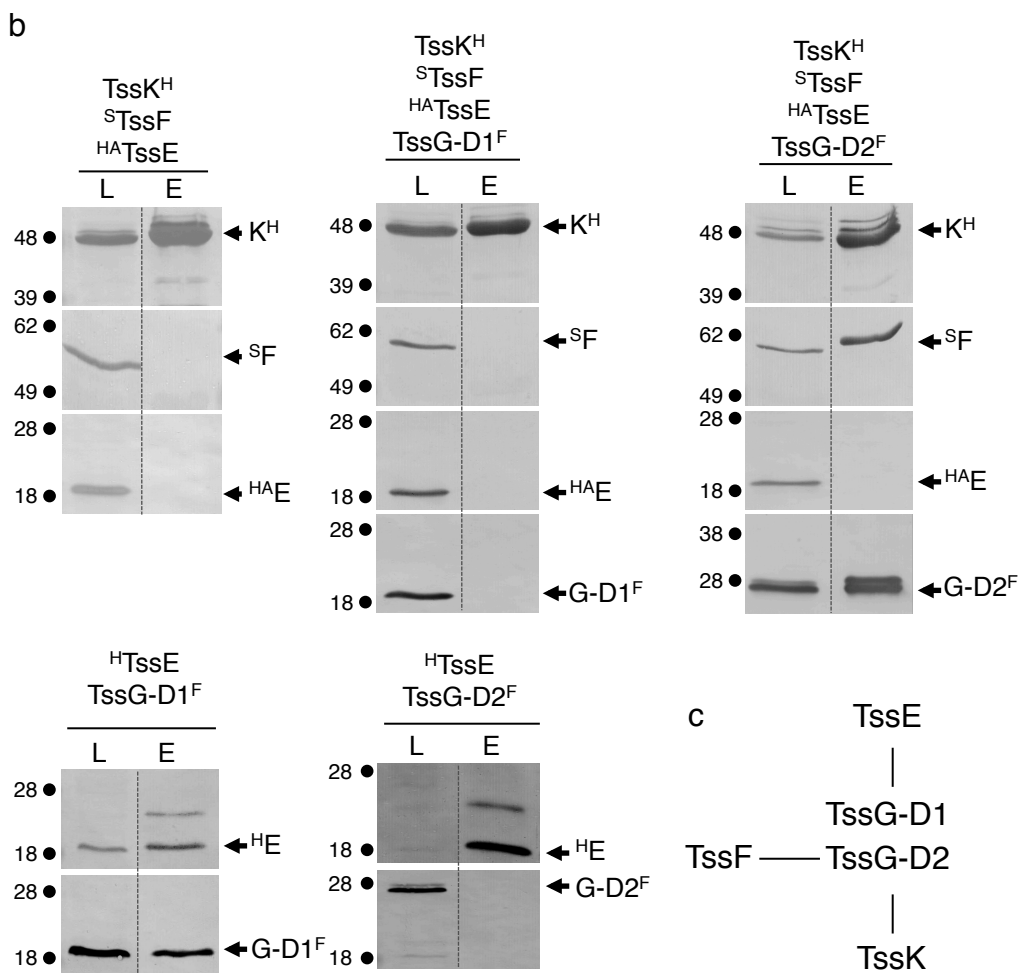

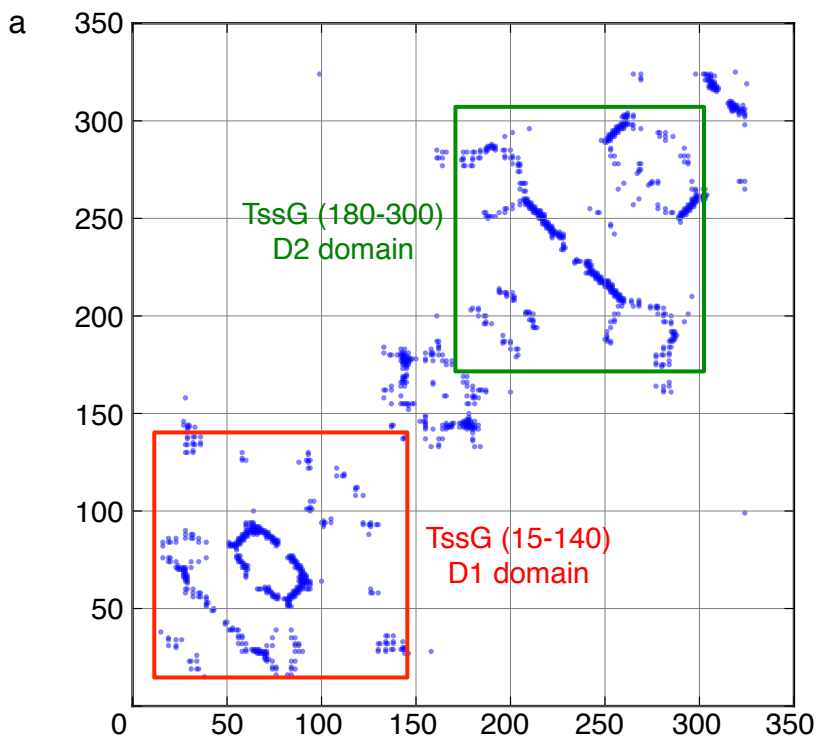

**Supplementary Figure 2. Protein-protein interaction network between the TssKFGE complex. Related to Figure 1.**

**a, b, and d.** Soluble extracts of *E. coli* BL21(DE3) cells producing the indicated protein were submitted to an affinity purification step on HisTrap or StrepTrap. The lysate (total soluble material, L), and eluate (E) were subjected to denaturing 12.5%-acrylamide polyacrylamide gel electrophoresis (PAGE) and immunodetected with the appropriate antibody. Immunodetected proteins are indicated in the right. Molecular weight markers (in kDa) are indicated in the left. Tags: H, 6×His; S, Strep-tag; F, FLAG; HA, hemagglutinin. In panel **d**, the result of the pairwise interaction is schematized (red cross indicates that no interaction is observed). Schematic summaries of panels **a-b** and **d** are shown in panels **c** and **e** respectively. Protein-protein interaction experiments have been performed independently twice and a representative result is shown.

**Supplementary Figure 3. Purification, biochemical characterization and stoichiometry analyses of the TssKFG and TssKFGE complexes. Related to Figure 1.**

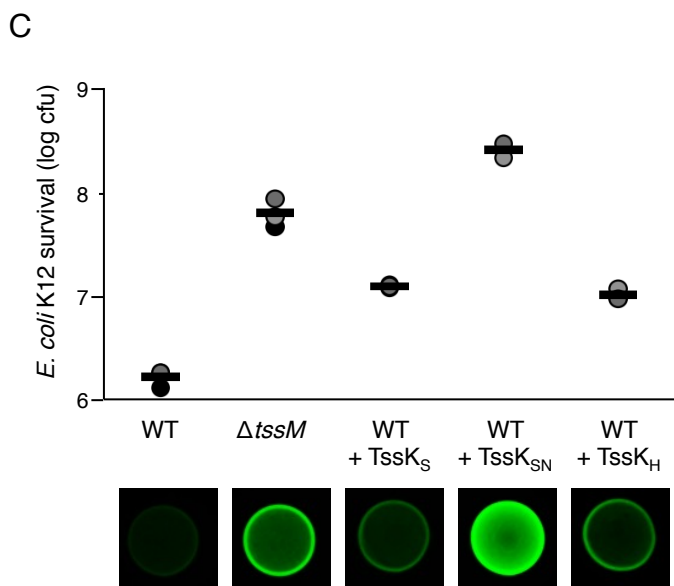

**a.** Left panel: Purified TssKFG complex subjected to sodium dodecyl sulfate 12.5%-acrylamide PAGE and Coomassie staining. The different proteins are indicated on the right, whereas molecular weight markers are indicated on the left. Right panel. Biochemical characterization of the TssKFG complex. Analytical size-exclusion chromatography analysis of the purified TssKFG complex (continuous line) on a Superose 6 column, calibrated with 43-, 75-, 158-, 440- and 660-kDa molecular mass markers (dotted lines). The molecular mass of each marker (in kDa) is indicated on the top of the corresponding peak. An arrow indicates the position of the peak fraction corresponding to the TssKFG complex. TssKFG complex purification and analytical size-exclusion chromatography analysis experiments were performed at least three times and a representative result is shown. **b-c.** Mass spectra of the TssKFGE (**b**) and TssKFG (**c**) complexes obtained in native conditions. The stoichiometry (indicated in red and blue for the TssKFGE and TssKFG complexes) were defined based on the comparison between theoretical ( $MW_{\text{theo}}$ ) and measured ( $MW_{\text{meas}}$ ) molecular weight markers. **d.** In-source dissociation (cone voltage: 150 V) of the TssKFGE complex obtained by collisional activation in native conditions. Native mass spectrometry and collisional activation experiments were performed 3 times and a representative result is shown.

**Supplementary Figure 4. TssG domain organization and interactions. Related to Figure 1.**

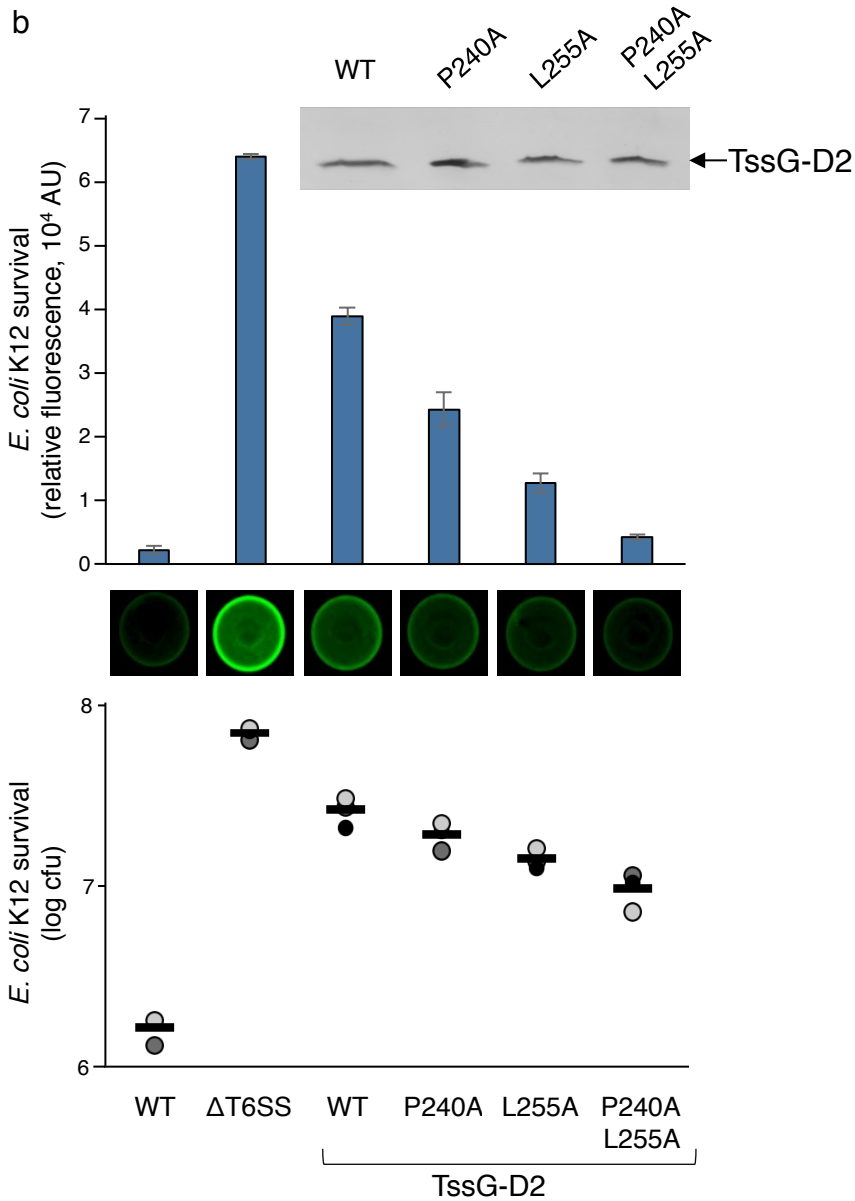

**a.** TssG residue contacts predicted by RaptorX<sup>24</sup> plotted into a contact map. X and Y axis are the residue indexes of TssG. Each blue dot is a predicted contact. The map is organized into two blocks of dense contacts located at the N- (TssG-D1, red, residues 15-140) and C-terminus (TssG-D2, green, residues 180-300). **b.** Soluble extracts of *E. coli* BL21(DE3) cells producing the indicated protein or domains were submitted to an affinity purification step on HisTrap. The lysate (total soluble material, L), and eluate (E) were subjected to denaturing 12.5%-acrylamide polyacrylamide gel electrophoresis (PAGE) and immunodetected with the appropriate antibody. Immunodetected proteins are indicated in the right. Molecular weight markers (in kDa) are indicated in the left. Tags: H, 6×His; S, Strep-tag; F, FLAG; HA, hemagglutinin. Protein-protein interaction experiments have been performed independently twice and a representative result is shown. **c.** Schematic summary of the interactions of TssG-D1 and -D2 with the TssKFE proteins.

## Supplementary Figure 5. Small Domain Interference analyses. Related to Figure 2.

**a-c.** Overproduction of TssK domains inhibits T6SS activity. **a.** Fluorescence microscopy recordings and statistical analyses of TssK<sub>sfGFP</sub> foci formation upon overproduction of TssK domains (TssK<sub>S</sub>, shoulder; TssK<sub>SN</sub>, shoulder and neck; TssK<sub>H</sub>, head). A representative image is shown on the bottom (white arrowheads indicate TssK<sub>sfGFP</sub> foci). The graph representing the percentage of cells with diffuse (green), and foci (blue) patterns is indicated on top (number of cells analyzed indicated on top of each bar). **b.** Fluorescence microscopy recordings and statistical analyses of TssB<sub>mCherry</sub> dynamics upon overproduction of TssK domains. A representative image is shown at the bottom (white arrowheads indicate dynamic TssB<sub>mCherry</sub> sheaths). The graph representing the percentage of cells with diffuse (light orange) and dynamic (orange) patterns is indicated on top (number of cells analyzed indicated on top of each bar). Microscopy analyses were performed independently three times, each in technical triplicate, and a representative experiment is shown. Scale bars, 1  $\mu\text{m}$ . **c.** Antibacterial assay. Gfp<sup>+</sup> kan<sup>R</sup> *E. coli* K-12 recipient cells were mixed with the indicated attacker cells, spotted onto Sci-1-inducing medium (SIM) agar plates supplemented with 0.05% L-arabinose, and incubated for 4 h at 37°C. The image of a representative bacterial spot is shown on the bottom and the number of recovered *E. coli* recipient cells is indicated in the upper graph (in log<sup>10</sup> of colony forming units (cfu)). The assays were performed from at least three independent cultures, with technical triplicates and a representative technical triplicate is shown. The circles indicate values from the technical triplicate, and the average is indicated by the bar. **d.** Purification of the TssKFGE complex upon overproduction of the TssK<sub>S</sub> and TssK<sub>SN</sub> domains. TssKFGE complexes were purified from cells overproducing TssK<sub>S</sub> (left panel) or TssK<sub>SN</sub> (right panel). The different proteins are indicated, as well as molecular weight markers (in kDa). Purification and sodium dodecyl sulphate 12,5%-acrylamide PAGE analysis were performed twice and a representative result is shown. **e.** The TssG-D2 domain interferes with T6SS antibacterial activity. Gfp<sup>+</sup> kan<sup>R</sup> *E. coli* K-12 recipient cells were mixed with the indicated attacker cells overproducing the indicated TssG domain, spotted onto Sci-1-inducing medium (SIM) agar plates supplemented with 0.05% L-arabinose, and incubated for 4 h at 37°C. The image of a representative bacterial spot is shown on bottom and the number of recovered *E. coli* recipient cells is indicated in the upper graph (in log<sup>10</sup> of colony forming units (cfu)). The circles indicate values from three independent assays, and the average is indicated by the bar.

**Supplementary Figure 6. TssG-TssK interaction. Related to Figure 2.**

**a.** TssG-TssK residue contacts predicted by EVcomplex plotted into contact maps. X and Y axis are the residue indexes of TssG and TssK (as indicated). Each blue and green dot is a predicted contact in TssK and TssG respectively. The residue pairs with the higher EVcomplex scores are indicated on right. **b.** Gfp<sup>+</sup> kan<sup>R</sup> *E. coli* K-12 recipient cells were mixed with the indicated attacker cells overproducing the indicated TssG-D2 variants, spotted onto Sci-1-inducing medium (SIM) agar plates supplemented with 0.05% L-arabinose, and incubated for 4 h at 37°C. The image of a representative bacterial spot is shown on the middle, the relative fluorescence of the spot (in arbitrary units, AU) is shown on the top graph whereas the number of recovered *E. coli* recipient cells is indicated in the lower graph (in log<sup>10</sup> of colony forming units (cfu)). The error bars represent the standard deviation across three independent assays. The circles indicate values from three independent assays, and the average is indicated by the bar. The levels of production of wild-type (WT) and mutant TssG-D2 variants is shown in the inset (SDS-PAGE and immunoblot analysis).

### **Supplementary Figure 7. Structures and domain interactions of the TssKFG proteins, Related to Figure 3**

**a.** Comparison between cryo-EM and crystal structures of TssK. Each TssK protomer is represented in the same orientation. For the cryo-EM structure, two protomers with different orientations for the C-terminal domain are presented (in brown and beige). For the crystal structure, the protomer for which the terminal domain could be built is presented (in green). **b.** Superimposition of cryo-EM and crystal structures of TssK. The same protomers as in A. are superimposed. **c.** Triangular hub at the top of the TssK shoulder domains. The three loops located between residues 105 to 145 define a triangle (in red) that encompasses the loop 1-18 and  $\alpha$ 1 helix bundle at the centre of the trimer (in yellow). **d.** Superimposition of the TssFa and TssFb protomers. TssFa and TssFb are represented as ribbons in cyan and blue respectively. Both protomers differ only by the position of the N-terminal antenna (indicated by the black arrow). **e.** Comparison between the TssFa and TssFb D1 domains and TssG body structures, shown in the same orientation. **f-g.** Interactions between the TssK1 (**f**) or TssK2 (**g**) trimer and TssG. The TssK protomers (green, beige and brown) and TssG feet and C-terminal extension are represented as surfaces. TssG antenna and body are represented as ribbons. TssG is in yellow with the exception of its C-terminal extension that is coloured in purple.

**Supplementary Figure 8. T6SS extended sheath bound to the baseplate. Related to Figure 4**

**a.** Fitting of the structure of the EAEK TssKFGE complex into the cryo-EM structure of the *V. cholerae* baseplate associated to a non-contractile sheath (EMD-3879). Left panel: side view highlighting one TssKFGE complex (ribbon diagram) fitted into the baseplate/sheath density (surface representation). Right panels: side (top) and bottom (bottom) slice of the TssKFGE complex fitted into the baseplate/sheath density. The bars correspond to 100 Å

**b.** Same representation of the EAEK baseplate and sheath models as in Figure 4a, with the location of the Hcp tube and VgrG spike from *V. cholerae*. The bar corresponds to 100 Å

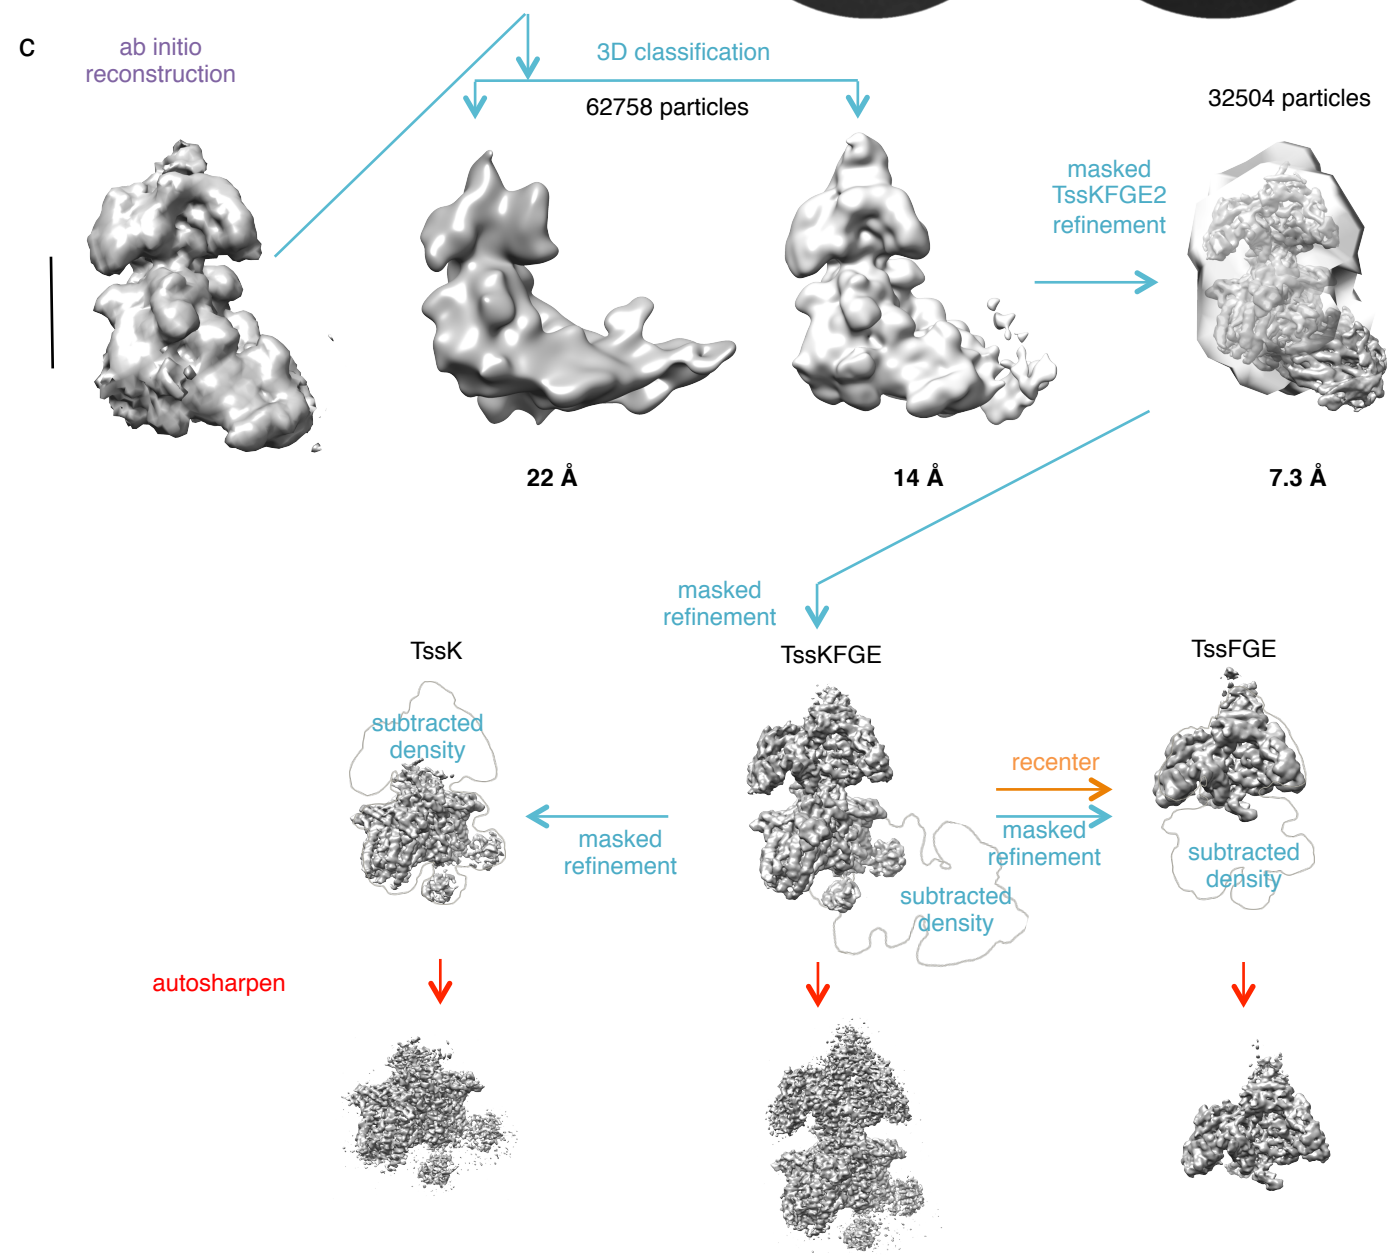

**c.** Ribbon diagram and surface representation of TssFa-TssFb belonging to two adjacent wedge complexes (main interface between wedge complexes within the T6SS baseplate). TssFa and TssFb are represented in cyan and blue respectively. The TssFa/Fb seen in Figure 4c is split open and the two protomers are placed in the same orientation. Within each subunit, the regions interacting with VgrG and TssBC are coloured in magenta and orange respectively. Left and middle panels display the same protomers rotated by 90° around their long axis. In the right panel, the protomers in ribbon diagram are shown in the same orientation as in the left panel.

**Supplementary Figure 9. Comparison of the bacteriophage T4 and T6SS baseplates. Related to Figure 5.**

**a.** Comparison between TssG and gp7 structures (ribbon diagram). The structural features conserved in both structures are represented in purple. The structural elements specific to each protein are represented in yellow. **b.** Comparison between TssF and gp6 structures (ribbon diagram). The structural features conserved in both structures are represented in purple (trimer scaffold) and green (wing domain). The structural elements specific to each protein are represented in blue. **c.** Interaction between TssFa and gp6a with the spike. For TssFa and gp6a, the same colour code as in panel B is used. Top row: for the T6SS, TssFa and VgrG are represented. For the T4 bacteriophage, gp6a, gp53 (grey) and gp27-gp5 are represented. For each, a ribbon diagram and surface representation of the same view (side view) is displayed on the left and right part respectively. Bottom row: surface representation of the same assemblies but without the spike (Top and bottom views on left and right respectively). **d.** Ribbon diagram of the T6SS wedge-TssBC interaction. The colour code used to identify the various subunits is the same as in Figure 4D (TssFa, cyan; TssFb, blue; TssG, yellow; TssE, green; TssBC, orange). The different protomers and domains are identified. **e.** Ribbon diagram of the bacteriophage T4 wedge-gp18 interaction. The different protomers and domains are identified.

**Supplementary Figure 10. Structure determination. Related to Figure 2.**

**a.** Representative cryo-micrograph of the purified TssKFGGE complex. The scale bar corresponds to 50 nm **b.** Typical 2D classes of the 4 different views of the complex in ice (scale bar, 100 nm). **c.** Flowchart of the cryo-EM processing procedure. The colour of the arrows represents the different software packages used (light blue, Relion; red, Phenix; violet, Cryosparc; orange, REP).

**Supplementary Figure 11. Analysis of model quality and refinement. Related to Figure 2.**

**a, d, and g.** Local resolution of the TssKFGE (**a**), TssFGE (**d**) and TssK (**g**) auto-sharpened densities. **b, e, and h.** Fourier shell correlation (FSC) of the final reconstruction of TssKFGE (**b**), TssFGE (**e**) and TssK (**h**). The resolution limit was calculated at the cut-off 0.143. **c, f, and i.** Model validation by comparison of the Fourier shell correlation (FSC) between model and half map 1 (work), model and half map 2 (free), and model versus full sharpened map (sum) plotted in red, green and purple respectively for of the TssKFGE (**c**), TssFGE (**f**) and TssK (**i**). **j.** Representative local density of an  $\alpha$ -helix (residues 19-33 of TssK chain H). **k.** Representative local density of a  $\beta$ -strand (residues 147-152 of TssK chain H).

TssG-D1

TssG-D2

TssF (495-585)

**Supplementary Figure 12. Structural modeling of TssF and TssG. Related to Figure 2.**

**a.** Flowchart of the structural modelling of TssG and TssF. **b.** Example of TssG contact map fit progressing with the different steps of the pipeline. The grey and orange dots are the predicted and model contacts, respectively, as defined in the supplementary methods text. **c.** Contact maps of the final TssK, TssG, and TssF structures compared to the corresponding predicted contact maps of the modelling pipeline. Green and red dots are predicted contacts in agreement and in disagreement with the structure, respectively. **d.** Ensemble of models for TssG-D1, TssG-D2 and TssF-D1 obtained from the predicted contacts and the ARIA modelling software (Step 3 of the pipeline). **e.** Fitting of the TssF and TssG structures in the postprocessed cryo-EM density (TssFGE), coloured according to B-factor values. The scale bar corresponds to 10 Å.
