28 **Abstract**

29 The novel coronavirus from China (SARS-CoV2) is spreading in the World, creating a huge reaction  
30 despite its current low incidence outside China and the far East. Moreover, it is not compared to the 4  
31 current circulating coronaviruses that cause millions of case in the World. Here, we compare incidence  
32 and death rate of these 4 common coronaviruses to that of SARS-COV2 in OECD countries. We  
33 conclude that the problem of SARS-CoV2 is probably overestimated so far, as 2,6 millions people die  
34 annually of respiratory infections versus less than 4000 for SARS-CoV2 so far.

37

## 38 **Introduction**

39 *Coronaviridae* represent a very important family of animal and human viruses (1; 2) that circulated  
40 permanently. These four common human coronaviruses (HKU1, NL63, OC43, E229) represent  
41 between 10 to 20% of respiratory infections worldwide and are present in all continents (3; 4; 5; 6; 7;  
42 8; 9; 10; 11; 12; 13; 14) (Table 3). Mortality is poorly assessed, but it is clear that there are chronic  
43 carriers as well as asymptomatic carriers. There are even two studies, one carried out by our team  
44 showing that there are as many asymptomatic carriers as symptomatic patients, and a second carried  
45 out in Ghana that shows that the number of asymptomatic carriers was not significantly different from  
46 the number of symptomatic carriers (3; 9). Since then, three epidemic episodes of emerging  
47 coronaviruses have been reported. The first, the SARS virus, has had very little impact on global  
48 morbidity and mortality since there have been more than 8000 recognized cases and 774 deaths (15;  
49 16). The second, MERS-Coronavirus, remained localized in Saudi Arabia, with a small epidemic of  
50 mainly nosocomial infections in South Korea (17). The MERS-Coronavirus, like SARS, have  
51 highlighted the major danger of nosocomial transmission to healthcare personnel who must absolutely  
52 be preserved in these epidemics (18). Finally, SARS-CoV-2 that appeared in December has expanded  
53 and has now affected more than 90,000 people worldwide (2; 19; 20). However, there is a significant  
54 number of cases only in the Far East so far. It is incontestably contagious since the example of a quasi-  
55 experimental study on the Diamond Princess cruise-ship that showed that if one locked up infected  
56 patients with uninfected patients, uninfected patients very quickly become infected in a confined  
57 world, and thus more 700 cases were diagnosed on this cruise-ship (21). However, commonly-  
58 circulating coronaviruses remain globally very predominant in the global situation because of their  
59 global distribution and their non-negligible mortality (22; 14). In this study, we wanted to share the  
60 experience of a reference laboratory representing around 1% of serious and diagnosed forms of  
61 respiratory infections, particularly seasonal, in France. This will allow evaluating the relative mortality  
62 of different human coronaviruses presented in hospitals in Marseille, compared to that of the Chinese  
63 coronavirus as it has appeared for the moment in countries with the same economic development,  
64 including France.

65

66 **Material and methods**

67 Assistance Publique – Hôpitaux de Marseille (AP-HM) is administrating all public hospitals in  
68 Marseille, France, including four university hospitals: La Timone hospital, Conception Hospital, North  
69 Hospital and South hospital, corresponding to 3,400 beds and 125,000 admissions each year (23). IHU  
70 Méditerranée Infection diagnosis laboratory is testing all samples from AP-HM in which respiratory  
71 viruses are suspected. The diagnosis is performed through molecular biology analysis. The results are  
72 monitored by a weekly automated surveillance system in IHU Méditerranée Infection, coupled to a  
73 laboratory information system (Nexlabs) (23). SARS-CoV-2 epidemiological data were obtained  
74 through an online platform gathering data from public agencies (24). Statistical analyses were  
75 performed by using BiostatGV online-software.

76

77

78 **Results**

79 In 2016, a total of 594 000 people deceased in France, among which 59,2% deceased in a care  
80 establishment (25). In 2016, a total of 2854 patients deceased in AP-HM hospitals. We can therefore  
81 estimate that each year, around 0,8% of people that deceased in care establishments in France died in  
82 AP-HM. This estimate allows us to have an idea of the number of peoples affected by a pathogen in  
83 France according to the number of people who died each year at the AP-HM.

84 From January, 1<sup>st</sup> 2013 to December, 31<sup>th</sup> 2019, 21 662 samples were tested by the AP-HM diagnosis  
85 laboratory. Among these, 770 samples were positive for coronavirus, of which 8 died (Mortality rate:  
86 1%). Among identified coronaviruses, 63 were identified as Coronavirus HKU1 (1 died, Mortality rate  
87 1.6%), 74 were identified as Coronavirus NL63 (2 died, Mortality rate 2.7%), 92 as Coronavirus E229  
88 (1 died, Mortality rate 1.1%) and 160 as Coronavirus OC43 (4 died, mortality rate 2.5%). 381  
89 Coronavirus, diagnosed before 2017, were not assigned to any of these four strains (Table 1).

90 We performed systematic testing (molecular biology) in the context of SARS-CoV-2 from January, 1<sup>st</sup>  
91 2020 to March, 2<sup>nd</sup> 2020, 7059 samples from patients presenting viral infections symptoms were  
92 tested by AP-HM diagnosis laboratory. Among them, 543 samples were positive to Coronavirus with  
93 2 deaths (Mortality rate: 0,36%): 277 were positive to Coronavirus HKU1, 146 Coronavirus NL63, 77  
94 to Coronavirus OC43, and 43 to Coronavirus 229E. No SARS-CoV-2 have been identified among  
95 these samples. One patient died with Coronavirus OC43 (Mortality rate 1,3%) and 1 patient died with  
96 Coronavirus HKU1 (Mortality rate 0,36%). No patients died with Coronavirus NL63 and E229 during  
97 this period.

98 During the same period, IHU Méditerranée Infection has been the regional center for the detection of  
99 the novel coronavirus SARS-CoV-2. A total of 596 analyses were performed on suspect patients since  
100 the emergence of the novel pathogen, among which 4 were positive to the SARS-CoV-2, and 709 were  
101 performed on French returnees from the Hubei province, all negative.

102 Until the 2<sup>nd</sup> of March 2020, a total of 90 307 patients were tested positive to SARS-CoV-2 in the  
103 world, among which 3086 died (mortality rate 3,4%). Including OECD countries only, 7476 patients  
104 were tested positive to SARS-CoV-2, among which 96 died (Mortality rate 1.3%) (Table 2). In France,  
105 191 people were tested positive, 3 died (Mortality rate 1,6%).

106 We compared the mortality rate of Coronavirus SARS-CoV-2 in OECD countries (1,3%) with the  
107 mortality rate of common coronaviruses identified in AP-HM patients (0,8%) from January 1st, 2013  
108 to March 2nd, 2020. We performed a  $\chi^2$  test on these values. The p-value was 0.11 (not significant).

109

110

## 111 Discussion

112 In this work, we highlight that the mortality of common Coronavirus infections is of 0.8% in France.  
113 This is to be compared with the mortality of the SARS-CoV-2 in the European or American developed  
114 countries of comparable economic level, which is of 1,3% (Table 2). If our extrapolation of deaths in  
115 AP-HM is true, in metropolitan France this would represent  $543 / 0.8 * 100 = 67,875$  cases of patients  
116 hospitalized with a respiratory infection with common coronaviruses in two months, almost as much  
117 as SARS-CoV-2 in the world. In fact, mortality from respiratory infections is extremely dependent on  
118 the quality of care and access to care, and severe forms have a better prognosis in countries with  
119 superior medical infrastructures. Under these conditions, there does not seem to be a significant  
120 difference in the mortality of Coronavirus SARS-CoV-2 in OECD countries with an economic level  
121 comparable to that of common coronaviruses ( $\chi^2$  test  $p=0.11$ ). Of course, the major flaw in this study  
122 is that the percentage of death attributable to the virus is not determined, but this is the case for all of  
123 the studies reporting respiratory virus infections, including those of SARS-CoV-2. Indeed, viral  
124 infections are ecosystem infections where the outcome depends on the inoculums and the surrounding  
125 microbiota (26). Thus, certain bacteria seem to be associated with symptomatic manifestations, such as  
126 *Streptococcus pneumoniae*, *Haemophilus influenzae*, and *Staphylococcus aureus*, which are known to  
127 be the bacteria causing an excess of mortality due to secondary infection. Finally, seasonality,  
128 geographic location, heat, humidity are co-factors, as are age, gender and underlying pathologies.  
129 Under these conditions and all other things being equal, the disease with SARS-CoV-2 cannot be  
130 described as being statistically more severe than that linked to currently circulating other  
131 coronaviruses .

132 Finally, in particular in OECD countries, the SARS-CoV-2 does not seem to be particularly deadlier  
133 than other circulating viruses. In addition to coronaviruses, there are 16 endemic viruses commonly  
134 circulating in developed countries (Adenovirus, Bocavirus, Cytomegalovirus, Enterovirus, Influenza A  
135 H1N1 virus, Influenza A H3N2 virus, Influenza B virus, Metapneumovirus, Parainfluenzae virus 1,  
136 Parainfluenzae virus 2, Parainfluenzae virus 3, Parainfluenzae virus 4, Parechovirus, Picornavirus,  
137 Rhinovirus, Syncytial respiratory virus) and 2.6 million deaths from respiratory infections (apart from  
138 tuberculosis) per year have been noted in recent years in the world (27). There is little chance that the

139 emergence of SARS-CoV-2 could change this statistic significantly. Fear could have a larger impact  
140 than the virus itself: a first case of suicide motivated by the fear of SARS-COV-2 has been reported in  
141 India (28).

142 In addition, coronaviruses that have rarely been tested systematically around the world may persist in  
143 the pharynx of asymptomatic people being a potential source of population immunity (29).

144 Furthermore, it should be noted that in systematic studies that have been carried out for other  
145 coronaviruses (but not yet for SARS-CoV-2), the percentage of asymptomatic carriers is equal or even  
146 higher as compared to symptomatic patients. We may soon have the same data for SARS-CoV-2,  
147 which will further reduce the relative risk associated with this specific pathology.
