25

26 *Abstract*27 **Background**

28 Chloroquine and hydroxychloroquine have been found to be efficient on SARS-CoV-2, and
29 reported to be efficient in Chinese COV-19 patients. We evaluate the role of
30 hydroxychloroquine on respiratory viral loads.

31 **Patients and methods**

32 French Confirmed COVID-19 patients were included in a single arm protocol from early
33 March to March 16th, to receive 600mg of hydroxychloroquine daily and their viral load in
34 nasopharyngeal swabs was tested daily in a hospital setting. Depending on their clinical
35 presentation, azithromycin was added to the treatment. Untreated patients from another center
36 and cases refusing the protocol were included as negative controls. Presence and absence of
37 virus at Day6-post inclusion was considered the end point.

38 **Results**

39 Six patients were asymptomatic, 22 had upper respiratory tract infection symptoms and eight
40 had lower respiratory tract infection symptoms.

41 Twenty cases were treated in this study and showed a significant reduction of the viral
42 carriage at D6-post inclusion compared to controls, and much lower average carrying duration
43 than reported of untreated patients in the literature. Azithromycin added to
44 hydroxychloroquine was significantly more efficient for virus elimination.

45 **Conclusion**

46 Despite its small sample size our survey shows that hydroxychloroquine treatment is
47 significantly associated with viral load reduction/disappearance in COVID-19 patients and its
48 effect is reinforced by azithromycin.

51 clinical trial

52

53 **1. Introduction**

54 In late December 2019, an outbreak of an emerging disease (COVID-19) due to a novel
55 coronavirus (named SARS-CoV-2 latter) started in Wuhan, China and rapidly spread in China
56 and outside [1,2]. The WHO declared the epidemic of COVID-19 as a pandemic on March
57 12th 2020 [3]. According to a recent Chinese stud, about 80% of patients present with mild
58 disease and the overall case-fatality rate is about 2.3% but reaches 8.0% in patients aged 70 to
59 79 years and 14.8% in those aged ≥ 80 years [4]. However, there is probably an important
60 number of asymptomatic carriers in the population, and thus the mortality rate is probably
61 overestimated. France is now facing the COVID-19 wave with more than 4500 cases, as of
62 March 14th 2020 [5]. Thus, there is an urgent need for an effective treatment to treat
63 symptomatic patients but also to decrease the duration of virus carriage in order to limit the
64 transmission in the community. Among candidate drugs to treat COVID-19, repositioning of
65 old drugs for use as antiviral treatment is an interesting strategy because knowledge on safety
66 profile, side effects, posology and drug interactions are well known [6,7].

67 A recent paper reported an inhibitor effect of remdesivir (a new antiviral drug) and
68 chloroquine (an old antimalarial drug) on the growth of SARS-CoV-2 *in vitro*, [8] and an
69 early clinical trial conducted in COVID-19 Chinese patients, showed that chloroquine had a
70 significant effect, both in terms of clinical outcome and viral clearance, when comparing to
71 controls groups [9,10]. Chinese experts recommend that patients diagnosed as mild, moderate
72 and severe cases of COVID-19 pneumonia and without contraindications to chloroquine, be
73 treated with 500 mg chloroquine twice a day for ten days [11].

74 Hydroxychloroquine (an analogue of chloroquine) has been demonstrated to have an anti-
75 SARS-CoV activity *in vitro* [12]. Hydroxychloroquine clinical safety profile is better than
76 that of chloroquine (during long-term use) and allows higher daily dose [13] and has fewer

77 concerns about drug-drug interactions [14]. Our team has a very comprehensive experience in
78 successfully treating patients with chronic diseases due to intracellular bacteria (Q fever due
79 to *Coxiella burnetii* and Whipple's disease due to *Tropheryma whipplei*) with long-term
80 hydroxychloroquine treatment (600 mg/day for 12 to 18 months) since more than 20 years.
81 [15,16] We therefore started to conduct a clinical trial aiming at assessing the effect of
82 hydroxychloroquine on SARS-CoV-2-infected patients after approval by the French Ministry
83 of Health. In this report we describe our early results, focusing on virological data in patients
84 receiving hydroxychloroquine as compared to a control group.

85

86 **2. Study population and Methods**

87 *Setting*

88 This ongoing study is coordinated by The Méditerranée Infection University Hospital Institute
89 in Marseille. Patients who were proposed a treatment with hydroxychloroquine were recruited
90 and managed in Marseille centre. Controls without hydroxychloroquine treatment were
91 recruited in Marseille, Nice, Avignon and Briançon centers, all located in South France.

92 *Patients*

93 Hospitalized patients with confirmed COVID-19 were included in this study if they fulfilled
94 two primary criteria: i) age >12 years; ii) PCR documented SARS-CoV-2 carriage in
95 nasopharyngeal sample at admission whatever their clinical status.

96 Patients were excluded if they had a known allergy to hydroxychloroquine or chloroquine or
97 had another known contraindication to treatment with the study drug, including retinopathy,
98 G6PD deficiency and QT prolongation. Breastfeeding and pregnant patients were excluded
99 based on their declaration and pregnancy test results when required.

100 *Informed consent*

101 Before being included in the study, patients meeting inclusion criteria had to give their consent
102 to participate to the study. Written informed signed consent was obtained from adult
103 participants (≥ 18 years) or from parents or legal guardians for minors (<18 years). An
104 information document that clearly indicates the risks and the benefits associated with the
105 participation to the study was given to each patient. Patients received information about their
106 clinical status during care regardless of whether they participate in the study or not. Regarding
107 patient identification, a study number was assigned sequentially to included participants,
108 according to the range of patient numbers allocated to each study centre. The study was
109 conducted in accordance with the International Council for Harmonisation of Technical
110 Requirements for Pharmaceuticals for Human Use (ICH) guidelines of good clinical practice,
111 the Helsinki Declaration, and applicable standard operating procedures.

112 The protocol, appendices and any other relevant documentation were submitted to the French
113 National Agency for Drug Safety (ANSM) (2020-000890-25) and to the French Ethic
114 Committee (CPP Ile de France) (20.02.28.99113) for reviewing and approved on 5th and 6th
115 March, 2020, respectively. This trial is registered with EU Clinical Trials Register, number
116 2020-000890-25.

117 *Procedure*

118 Patients were seen at baseline for enrolment, initial data collection and treatment at day-0, and
119 again for daily follow-up during 14 days. Each day, patients received a standardized clinical
120 examination and when possible, a nasopharyngeal sample was collected. All clinical data were
121 collected using standardized questionnaires. All patients in Marseille center were proposed oral
122 hydroxychloroquine sulfate 200 mg, three times per day during ten days (in this preliminary
123 phase ,we did not enrolled children in the treatment group based in data indicating that children
124 develop mild symptoms of COVID-19 [4]). Patients who refused the treatment or had an

125 exclusion criteria, served as controls in Marseille centre. Patients in other centers did not receive
126 hydroxychloroquine and served as controls. Symptomatic treatment and antibiotics as a
127 measure to prevent bacterial super-infection was provided by investigators based on clinical
128 judgment. Hydroxychloroquine was provided by the National Pharmacy of France on
129 nominative demand.

130 *Clinical classification*

131 Patients were grouped into three categories: asymptomatic, upper respiratory tract infection
132 (URTI) when presenting with rhinitis, pharyngitis, or isolated low-grade fever and myalgia, and
133 lower respiratory tract infections (LRTI) when presenting with symptoms of pneumonia or
134 bronchitis.

135 *PCR assay*

136 SARS-CoV-2 RNA was assessed by real-time reverse transcription-PCR [17].

137 *Hydroxychloroquine dosage*

138 Native hydroxychloroquine has been dosed from patients' serum samples by UHPLC-UV using
139 a previously described protocol [18]. The peak of the chromatogram at 1.05 min of retention
140 corresponds to hydroxychloroquine metabolite. The serum concentration of this metabolite is
141 deduced from UV absorption, as for hydroxychloroquine concentration. Considering both
142 concentrations provides an estimation of initial serum hydroxychloroquine concentration.

143

144

145

146 *Culture*

147 For all patients, 500 μ L of the liquid collected from the nasopharyngeal swab were passed
148 through 0.22- μ m pore sized centrifugal filter (Merck millipore, Darmstadt, Germany), then
149 were inoculated in wells of 96-well culture microplates, of which 4 wells contained Vero E6
150 cells (ATCC CRL-1586) in Minimum Essential Medium culture medium with 4% fetal calf
151 serum and 1% glutamine. After centrifugation at 4,000 g, microplates were incubated at 37°C.
152 Plates were observed daily for evidence of cytopathogenic effect. Presumptive detection of
153 virus in supernatant was done using SU5000 SEM (Hitachi) then confirmed by specific RT-
154 PCR.

155 *Outcome*

156 The primary endpoint was virological clearance at day-6 post-inclusion. Secondary outcomes
157 were virological clearance overtime during the study period, clinical follow-up (body
158 temperature, respiratory rate, long of stay at hospital and mortality), and occurrence of side-
159 effects.

160 *Statistics*

161 Assuming a 50% efficacy of hydroxychloroquine in reducing the viral load at day 7, a 85%
162 power, a type I error rate of 5% and 10% loss to follow-up, we calculated that a total of 48
163 COVID-19 patients (ie, 24 cases in the hydroxychloroquine group and 24 in the control group)
164 would be required for the analysis (Fleiss with CC). Statistical differences were evaluated by
165 Pearson's chi-square or Fisher's exact tests as categorical variables, as appropriate. Means of
166 quantitative data were compared using Student's t-test. Analyses were performed in Stata
167 version 14.2.

168

169 **3. Results** (detailed results are available in supplementary Table 1)

170 *Demographics and clinical presentation*

171 We enrolled 36 out of 42 patients meeting the inclusion criteria in this study that had at least
172 six days of follow-up at the time of the present analysis. A total of 26 patients received
173 hydroxychloroquine and 16 were control patients. Six hydroxychloroquine-treated patients
174 were lost in follow-up during the survey because of early cessation of treatment. Reasons are
175 as follows: three patients were transferred to intensive care unit, including one transferred on
176 day2 post-inclusion who was PCR-positive on day1, one transferred on day3 post-inclusion
177 who was PCR-positive on days1-2 and one transferred on day4 post-inclusion who was PCR-
178 positive on day1 and day3; one patient died on day3 post inclusion and was PCR-negative on
179 day2; one patient decided to leave the hospital on day3 post-inclusion and was PCR-negative
180 on days1-2; finally, one patient stopped the treatment on day3 post-inclusion because of nausea
181 and was PCR-positive on days1-2-3. The results presented here are therefore those of 36
182 patients (20 hydroxychloroquine-treated patients and 16 control patients). None of the control
183 patients was lost in follow-up. Basic demographics and clinical status are presented in Table 1.
184 Overall, 15 patients were male (41.7%), with a mean age of 45.1 years. The proportion of
185 asymptomatic patients was 16.7%, that of patients with URTI symptoms was 61.1% and that
186 of patients with LRTI symptoms was 22.2%). All patients with LRTI symptoms, had confirmed
187 pneumonia by CTScan. Hydroxychloroquine-treated patients were older than control patients
188 (51.2 years vs. 37.3 years). No significant difference was observed between
189 hydroxychloroquine-treated patients and control patients with regard to gender, clinical status
190 and duration of symptoms prior to inclusion (Table 1). Among hydroxychloroquine-treated
191 patients six patients received azithromycin (500mg on day1 followed by 250mg per day, the
192 next four days) to prevent bacterial super-infection under daily electrocardiogram control.
193 Clinical follow-up and occurrence of side-effects will be described in a further paper at the end
194 of the trial.

195 *Hydroxychloroquine dosage*

196 Mean hydroxychloroquine serum concentration was $0.46 \mu\text{g/ml} \pm 0.2$ (N=20).

197 *Effect of hydroxychloroquine on viral load*

198 The proportion of patients that had negative PCR results in nasopharyngeal samples
199 significantly differed between treated patients and controls at days 3-4-5 and 6 post-inclusion
200 (Table 2). At day6 post-inclusion, 70% of hydroxychloroquine-treated patients were
201 virologically cured comparing with 12.5% in the control group ($p= 0.001$).

202 When comparing the effect of hydroxychloroquine treatment as a single drug and the effect of
203 hydroxychloroquine and azithromyc in combination, the proportion of patients that had
204 negative PCR results in nasopharyngeal samples was significantly different between the two
205 groups at days 3-4-5 and 6 post-inclusion (Table 3). At day6 post-inclusion, 100% of patients
206 treated with hydroxychloroquine and azithromycin combination were virologically cured
207 comparing with 57.1% in patients treated with hydroxychloroquine only, and 12.5% in the
208 control group ($p<0.001$). These results are summarized in Figures 1 and 2. Drug effect was
209 significantly higher in patients with symptoms of URTI and LRTI, as compared to
210 asymptomatic patients with $p<0.05$ (data not show).

211 Of note, one patient who was still PCR-positive at day6-post inclusion under
212 hydroxychloroquine treatment only, received azithromycin in addition to hydroxychloroquine
213 at day8-post inclusion and cured her infection at day-9 post infection. In contrast, one of the
214 patients under hydroxychloroquine and azithromycin combination who tested negative at
215 day6 post-inclusion was tested positive at low titer at day8 post-inclusion.

216 *Cultures*

217 We could isolate SARS-CoV-2 in 19 out of 25 clinical samples from patients.

218

219 **4. Discussion**

220 For ethical reasons and because our first results are so significant and evident we decide to
221 share our findings with the medical community, given the urgent need for an effective drug
222 against SARS-CoV-2 in the current pandemic context.

223 We show here that hydroxychloroquine is efficient in clearing viral nasopharyngeal carriage
224 of SARS-CoV-2 in COVID-19 patients in only three to six days, in most patients. A
225 significant difference was observed between hydroxychloroquine-treated patients and controls
226 starting even on day3 post-inclusion. These results are of great importance because a recent
227 paper has shown that the mean duration of viral shedding in patients suffering from COVID-
228 19 in China was 20 days (even 37 days for the longest duration) [19]

229 Very recently, a Chinese team published results of a study demonstrating that chloroquine and
230 hydroxychloroquine inhibit SARS-CoV-2 *in vitro* with hydroxychloroquine
231 ($EC_{50}=0.72\% \mu M$) found to be more potent than chloroquine ($EC_{50}=5.47\% \mu M$) [14]. These
232 *in vitro* results corroborate our clinical results. The target values indicated in this paper [14]
233 were reached in our experiments. The safer dose-dependent toxicity profile of
234 hydroxychloroquine in humans, compared to that of chloroquine [13] allows using clinical
235 doses of hydroxychloroquine that will be over its EC_{50} observed *in vitro* [14].

236 Our preliminary results also suggest a synergistic effect of the combination of
237 hydroxychloroquine and azithromycin. Azithromycin has been shown to be active *in vitro*
238 against Zika and Ebola viruses [20-22] and to prevent severe respiratory tract infections when
239 administrated to patients suffering viral infection [23]. This finding should be further explored
240 to know whether a combination is more effective especially in severe cases. Speculated
241 potential risk of severe QT prolongation induced by the association of the two drugs has not

242 been established yet but should be considered. As for each treatment, the cost benefits of the
243 risk should be evaluated individually. Further studies on this combination are needed, since
244 such combination may both act as an antiviral therapy against SARS-CoV-2 and prevent
245 bacterial super-infections.

246 The cause of failure for hydroxychloroquine treatment should be investigated by testing the
247 isolated SARS-CoV-2 strains of the non-respondents and analyzing their genome, and by
248 analyzing the host factors that may be associated with the metabolism of hydroxychloroquine.
249 The existence of hydroxychloroquine failure in two patients (mother and son) is more
250 suggestive of the last mechanism of resistance.

251 Such results are promising and open the possibility of an international strategy to decision-
252 makers to fight this emerging viral infection in real-time even if other strategies and research
253 including vaccine development could be also effective, but only in the future. We therefore
254 recommend that COVID-19 patients be treated with hydroxychloroquine and azithromycin to
255 cure their infection and to limit the transmission of the virus to other people in order to curb
256 the spread of COVID-19 in the world. Further works are also warranted to determine if these
257 compounds could be useful as chemoprophylaxis to prevent the transmission of the virus,
258 especially for healthcare workers. Our study has some limitations including a small sample
259 size, limited long-term outcome follow-up, and dropout of six patients from the study,
260 however in the current context, we believe that our results should be shared with the scientific
261 community.

262

367 **Titles for figures**

368 **Figure 1.** Percentage of patients with PCR-positive nasopharyngeal samples from inclusion to
369 day6 post-inclusion in COVID-19 patients treated with hydroxychloroquine and in COVID-
370 19 control patients.

371 **Figure 2.** Percentage of patients with PCR-positive nasopharyngeal samples from inclusion to
372 day6 post-inclusion in COVID-19 patients treated with hydroxychloroquine only, in COVID-
373 19 patients treated with hydroxychloroquine and azithomycin combination, and in COVID-19
374 control patients.

Table 1 Characteristics of the study population.

	Age (years)			Male gender		Clinical status				Time between onset of symptoms and inclusion (days)		
	Mean \pm SD	t	p-value	n (%)	p-value	Asymptomatic	URTI	LRTI	p-value	Mean \pm SD	t	p-value
Hydroxychloroquine treated patients (N=20)	51.2 \pm 18.7	-1.95	0.06	9 (45.0)	0.65	2 (10.0)	12 (60.0)	6 (30.0)	0.30	4.1 \pm 2.6	-0.15	0.88
Control patients (N=16)	37.3 \pm 24.0			6 (37.5)		4 (25.0)	10 (62.5)	2 (12.5)		3.9 \pm 2.8		
All patients (36)	45.1 \pm 22.0			15 (41.7)		6 (16.7)	22 (61.1)	8 (22.2)		4.0 \pm 2.6		

URTI: upper tract respiratory infection, LRTI: lower tract respiratory infection

Table 2. Proportion of patients with virological cure (negative nasopharyngeal PCR) by day, in COVID-19 patients treated with hydroxychloroquine and in COVID-19 control patients.

	Day3 post inclusion			Day4 post inclusion			Day5 post inclusion			Day6 post inclusion		
	Number of negative patients/total number of patients	%	p-value	Number of negative patients/total number of patients	%	p-value	Number of negative patients/total number of patients	%	p-value	Number of negative patients/total number of patients	%	p-value
Hydroxychloroquine treated patients (N=20)	10/20	50.0	0.005	12/20	60.0	0.04	13/20	65.0	0.006	14/20	70.0	0.001
Control patients (N=16)	1/16	6.3		4/16	25.0		3/16	18.8		2/16	12.5	

^acontrol patients from centers other than Marseille did not underwent daily sampling, but were sampled every other day in most cases, they were considered positive for PCR when actually positive the day(s) before and the day(s) after the day(s) with missing data.

Table 3. Proportion of patients with virological cure (negative nasopharyngeal PCR) by day, in COVID-19 patients treated with hydroxychloroquine only, in COVID-19 patients treated with hydroxychloroquine and azithromycin combination, and in COVID-19 control patients.

	Day3 post inclusion			Day4 post inclusion			Day5 post inclusion			Day6 post inclusion		
	Number of negative patients/total number of patients	%	p-value	Number of negative patients/total number of patients	%	p-value	Number of negative patients/total number of patients	%	p-value	Number of negative patients/total number of patients	%	p-value
Control patients	1/16	6.3	0.002	4/16	25.0	0.05	3/16	18.8	0.002	2/16	12.5	<0.001
Hydroxychloroquine treatment only	5/14	35.7		7/14	50.0		7/14	50.0		8/14	57.1	
Hydroxychloroquine and azithromycin combined treatment	5/6	83.3		5/6	83.3		6/6	100		6/6	100	

Supplementary Table 1.
