The mammalian heart arises from various populations of Mesp1-expressing cardiovascular progenitors (CPs) that are specified during the early stages of gastrulation. Mesp1 is a transcription factor (TF) that acts as a master regulator of CP specification and differentiation. However, how Mesp1 regulates the chromatin landscape of nascent mesodermal cells to define the temporal and spatial patterning of the distinct populations of CPs remains unknown. Here, by combining ChIP-seq, RNA-seq and ATAC-seq during mouse pluripotent stem cell differentiation, we defined the dynamic remodelling of the chromatin landscape mediated by Mesp1. We identified different enhancers that are temporally regulated to erase the pluripotent state and specify the pools of CPs that mediate heart development. We identified Zic2 and Zic3 as essential cofactors that act with Mesp1 to regulate its TF activity at key mesodermal enhancers, thereby regulating the chromatin remodelling and gene expression associated with the specification of the different populations of CPs *in vivo*. Our study identifies the dynamics of the chromatin landscape and enhancer remodelling associated with temporal patterning of early mesodermal cells into the distinct populations of CPs that mediate heart development.

Introduction

During embryogenesis, tight temporal and spatial control of transcription is needed to correctly assign cell identities throughout the developing body. At the onset of gastrulation, epiblast cells shut down the gene regulatory network of the pluripotent state and start expressing genes specific to the different cell fates that are progressively specified. The transcription factors (TFs) that govern these cell fate transitions are relatively well known. However, how these lineage-specific master TFs control the temporal and spatial remodelling of the chromatin and enhancer landscape that mediate downstream gene expression to allocate the different cell fates at the correct place and time during embryonic development remain poorly understood.

The mammalian heart is the first organ to form during development, as it is essential for embryonic survival. It is a complex organ composed of four chambers and various cell lineages including cardiomyocytes (CMs), endocardial cells (ECs), fibroblasts and smooth muscle cells (SMCs)^{1,2}. The different regions of the heart (ventricles, atria and outflow tract) arise from the differentiation of distinct pools of cardiovascular progenitors (CPs) that are specified in a precise temporal and spatial pattern during gastrulation^{3,4}. Patterning defects during CP specification and differentiation lead to congenital heart disease, which represents the major cause of birth defects in humans⁵⁻⁷.

Mesp1, a bHLH TF, is the earliest marker of CPs. Mesp1 is expressed transiently during mouse gastrulation in CPs that will contribute to all heart regions and cardiovascular cell types⁸⁻¹². In mouse pluripotent stem cells (PSCs), Mesp1 directly promotes the expression of many TFs that compose the core gene regulatory network of cardiovascular development¹³⁻¹⁶. Lineage tracing experiments revealed that temporally distinct Mesp1⁺ CPs give rise to different heart regions and cardiovascular lineages^{11,17}. Moreover, scRNA-seq of Mesp1-expressing cells during mouse gastrulation *in vivo* demonstrated that Mesp1 CPs are temporally and

spatially pre-patterned into progenitors of the different heart regions and cardiovascular lineages during the early stages of mouse gastrulation^{12, 18, 19}. The chromatin landscape and enhancer remodelling mediated by *Mesp1* that promotes the specification of these different cardiovascular lineages and heart regions in a spatially and temporally regulated manner remains unknown.

Here, we define the precise dynamics of chromatin remodelling and enhancer logic by which *Mesp1* temporally regulates gene expression programs during CP specification and differentiation *in vitro* and *in vivo*. Using RNA-seq, ChIP-seq and ATAC-seq, we found that *Mesp1* induces remodelling of the chromatin and enhancer landscape to promote dynamic patterns of gene expression during development. We also identified *Zic2* and *Zic3* as regulators of *Mesp1* TF activity at key mesodermal enhancers, promoting in a cooperative manner *Mesp1* binding to the chromatin, chromatin remodelling and regulation of gene expression, allowing the specification and differentiation of CPs during the early stages of mouse gastrulation.

Results

Temporal regulation of gene expression mediated by Mesp1

To define the temporality of gene expression mediated by Mesp1, we performed RNA-seq during differentiation of mouse PSCs, 12 and 24 hours after doxycycline (dox)-induced Mesp1 expression at day 2.5 of embryoid body (EB) differentiation, slightly earlier than *Mesp1* endogenous expression (Fig. 1a). Mesp1 RNA-FISH showed that dox-mediated Mesp1 overexpression induces *Mesp1* expression in almost every cell (89 +/- 2 %) within the EB whereas only 22 +/- 4% of the cells express *Mesp1* in control conditions at day (D) 3.5. Mesp1 expression per cell was on average 2.2 higher in dox compared to control conditions (Extended Data Fig. 1a-c). Our temporal analysis of gene expression showed that Mesp1 induces distinct patterns of expression that could be divided into different classes: genes that were rapidly and transiently (between 0 and 12 hours) induced by Mesp1 called “early genes” (e.g. *Snail*), genes whose expression increased constantly between 0 and 24 hours called “constant genes”, (e.g. *Pdgfra*) or genes activated only after 24 hours called “late genes” (e.g. *Hoxb1*). A similar temporal pattern of early, constant and late downregulated genes could be identified (Fig. 1b-d, Extended data Fig 1d-f). Interestingly, the genes that were expressed at higher levels in E6.75 *Mesp1*⁺ CPs *in vivo*¹¹ were mostly categorized as early upregulated *in vitro*, whereas the genes enriched at E7.25 were mostly classified as constant or late upregulated genes *in vitro* (Fig. 1e-h), showing that the temporality of Mesp1-regulated genes during PSC differentiation *in vitro* recapitulates the temporality of gene expression found during gastrulation *in vivo*.

Dynamics of chromatin and enhancer remodelling regulated by Mesp1

To investigate the temporal dynamics by which Mesp1 induces chromatin and enhancer remodelling associated with CP progenitor specification, we assessed the temporality of Mesp1 binding after its induction during PSC differentiation. To this end, we performed Mesp1 ChIP-

seq 12 and 24 hours after overexpression of triple-HA tagged Mesp1 in PSCs induced at day 2.5 of embryonic bodies (EBs) differentiation (Fig. 1a and 2a). We defined a total of 2011 high-quality peaks, out of which 823 peaks were detected at 12 hours and 1792 peaks at 24 hours ($p < 10^{-10}$). The majority of these peaks were located either in intergenic regions or introns, with only 4% of peaks located at a transcriptional start site, demonstrating that Mesp1 acts as a lineage-specific TF through binding to distal regulatory elements (Extended Data Fig. 2a). We found that 536/1368 (39%) of upregulated genes presented a Mesp1 ChIP-seq peak within 500 kb of their transcription start site, versus 194/1448 (13%) of downregulated genes, suggesting that Mesp1 acts mainly as a transcriptional activator (Fig. 2a-c).

Mesp1 ChIP-seq peaks could be classified into early (36/2011) (2%), constant (1451/2011) (72%), and late Mesp1 binding sites (525/2011) (26%). The kinetics of Mesp1 binding correlated with kinetics of gene expression, with early peaks being mostly associated with early upregulated genes, and late peaks with late upregulated genes (Fig. 2a-e).

To define how Mesp1 binding to its target sites affects the remodelling of the chromatin landscape, we performed ATAC-seq and histone 3 lysine 27 acetyl (H3K27Ac) ChIP-seq at 0, 12 and 24h following Mesp1 expression. Binding of Mesp1 to the regulatory regions of its target genes induced an opening of the chromatin, as defined by ATAC-seq, as well as an acetylation of histone 3 at lysine 27 (H3K27Ac and monomethylation of histone 3 at lysine 4 (H3K4me1) on neighbouring nucleosomes, two post-translational histone modifications associated with active enhancers (Fig. 2f-g)^{20, 21}. Mesp1 promoted the opening of chromatin regions that were previously closed in the absence of Mesp1 expression at the majority (74%) of its binding sites (Fig. 2f-g), which we called *de novo* peaks. The remaining Mesp1-bound peaks were located in chromatin regions previously opened before Mesp1 binding, called primed peaks (21%) or that did not present detectable chromatin opening in any condition (5%). Positional analysis of nucleosomes in ATAC-seq data at Mesp1 binding sites confirmed that

68% of Mesp1-bound peaks were at least partially occluded by nucleosomes without Mesp1 induction, versus 13% after Mesp1 expression (Fig. 2h). Chromatin opening at these sites was associated with the temporality of Mesp1 binding, as only 20% of early Mesp1-bound peaks were classified as *de novo* peaks, versus 70% of constant and 87% of late peaks (Fig. 2i). The dynamics of chromatin remodelling and the temporality of H3K27Ac deposition around Mesp1-bound enhancers followed the kinetics of Mesp1 binding (Extended Data Fig. 2b-d).

We defined Mesp1-bound enhancers as DNA regions not located within a promoter that are bound by Mesp1, present opening of the chromatin, are flanked by histones marked with H3K27Ac and H3K4Me1, and are associated with upregulation of gene expression following Mesp1 induction. To functionally validate the role of these putative enhancers, we deleted using CRISPR/Cas9 different Mesp1 binding regions (+/- 500 bp) presenting the hallmarks of enhancer activation after Mesp1 induction in regulatory regions of three different direct Mesp1 target genes that are important during cardiovascular development (*Hoxb1*, *Hand1*, and *Myocardin*). Deletion of a single Mesp1-bound putative enhancer strongly decreased the ability of Mesp1 to upregulate these target genes (Fig. 3b).

Different TFs are associated with temporally regulated Mesp1-bound enhancers

To define which TFs could cooperate with Mesp1 to control the different temporal patterns of gene expression induced by Mesp1, we performed motif discovery at Mesp1 ChIP-seq peaks using Homer²². Most Mesp1 ChIP-seq peaks (88%) presented a very specific E-box motif: CAAATGG (Fig. 3c), equally present in early, constant and late ChIP-seq peaks, but significantly enriched in *de novo* peaks (90%) versus primed peaks (71%). This motif was strongly over-represented in comparison to other bHLH motifs in DNA footprints defined by ATAC-seq within Mesp1-bound enhancers (Extended Data Fig. 3a-c). The extra G next at the

3' end of the E-box motif is also found in the binding site of *Ascl1*, a bHLH pioneer TF promoting reprogramming of fibroblasts to neuronal cell fate^{23,24}.

Mesp1-bound enhancers contained on average five bHLH binding motifs. To assess the importance of the most over-represented bHLH motif with an extra G within *Mesp1* binding sites, we replaced one CAAATGG motif by GCTAGCG in the *Pdgfra* proximal enhancer, using CRISPR/Cas9-mediated homology directed repair (Fig. 3d). We showed that replacement of this single motif decreased by 3-fold the ability of *Mesp1* to induce *Pdgfra* expression both at the transcriptional and protein level, demonstrating that this binding site is important for enhancer activity mediated by *Mesp1* (Fig. 3e-g).

In addition to *Mesp1* bHLH binding sites, we found a significant enrichment for binding motifs corresponding to other families of TFs, including *Zic*, *Sox*, *Tcf/Lef*, *Oct/Sox/Nanog*, *Gata* and *Fox* motifs (Fig. 3c). Not all motifs were equally present in early, constant and late *Mesp1* binding peaks, with a significant enrichment of a compound binding site of pluripotency TFs *Oct4*, *Sox2* and *Nanog* in early peaks and an increased proportion of late peaks containing *FOX* and *GATA* motifs (Extended Data Fig. 3a).

Many TFs that have their binding motif enriched in *Mesp1* ChIP-seq peaks are themselves upregulated by *Mesp1* (e.g. *Gata4*, *Hand1/2*, *Meis1/2*, *Hoxb1*, *Foxc1/2*) and are known to play roles later during cardiovascular development (Fig. 3h)²⁵⁻³⁰. Moreover, a fraction of the enhancers that become active at 24 hours following *Mesp1* expression were not directly bound by *Mesp1* (23%, 899/3839), suggesting that additional TFs acting downstream of *Mesp1* are activated and induce chromatin remodelling. *GATA* binding sites were the most enriched motifs in ATAC-seq peaks opened by *Mesp1* but not directly bound by *Mesp1*. Analysis of *Gata4* ChIP-seq performed in mesodermal cells derived from mouse PSCs showed that *Gata4* binds a fraction of the enhancers bound by *Mesp1* (11%)³¹, the majority of which were predicted

by motif discovery. In addition, Gata4 also bound to many (49%, 444/899) of the enhancers that are opened following Mesp1 induction but not directly bound by Mesp1, most of them (75%) being predicted from our bioinformatic analysis (Extended Data Fig. 3d-f).

We also found 2772 peaks that were associated with a closing of the chromatin and lower levels of flanking H3K27Ac without presenting Mesp1 binding. These peaks were found in the vicinity of downregulated genes, including pluripotency TFs *Oct4* and *Sox2* and epithelial genes *Cdh1* and *Epcam*. Motif enrichment analysis on these repressed peaks revealed strong enrichment of a Oct4-Sox2-Tcf-Nanog compound motif. Sox2, Oct4 and Nanog ChIP-seq³² showed that these core pluripotency TFs bound around 60% of enhancers that were indirectly repressed by Mesp1 (Extended Data Fig. 4a-d).

Chromatin landscape and transcriptional regulation at physiological level of Mesp1

To assess whether these findings are relevant in the absence of Mesp1 overexpression, we performed RNA-seq and ATAC-seq on Flk1/Pdgfra double positive and double negative cells at day 4 of PSC differentiation (Figure 4a), which are enriched for endogenous Mesp1 expression during mouse and human PSC differentiation *in vitro* and mouse gastrulation *in vivo*^{11, 33, 34}. First, we found that 32% of the genes upregulated by Mesp1 were significantly enriched in Flk1⁺/Pdgfra⁺ cells. On the other hand, 60% of the genes downregulated by Mesp1 were depleted in Flk1⁺/Pdgfra⁺ cells (Figure 4b-d). ATAC-seq on FACS-isolated Flk1⁺/Pdgfra⁺ and Flk1⁻/Pdgfra⁻ cells showed that 44% of Mesp1-bound sites were opened in Flk1⁺/Pdgfra⁺ cells, 50% of which (435/2011) were significantly enriched in Flk1⁺/Pdgfra⁺ cells (Figure 4e-g). Motif discovery on all peaks enriched in Flk1⁺/Pdgfra⁺ cells revealed strong enrichment of GATA, T-box and Mesp1 motifs (Figure 4h), showing that the same genes, enhancers and their associated TFs were enriched in Mesp1-expressing cells in the absence of Mesp1 overexpression.

Cell context dependency of Mesp1 binding and gene regulation

To define the importance of the cellular context for Mesp1 binding and transcriptional regulation, we induced Mesp1 overexpression in PSCs cultured in 2i medium, a condition that promotes the naïve pluripotent state³⁵, and performed Mesp1 ChIP-seq, RNA-seq, and ATAC-seq. We found that only 6/1368 (0.4%) of Mesp1 target genes were significantly upregulated 24 hours after Mesp1 overexpression in 2i. In 2i conditions, Mesp1 significantly bound to 13% of its binding sites identified during PSC differentiation, although low level of Mesp1 binding occurred at many of its binding sites. The proportion of primed versus de novo binding sites in 2i was similar than during PSC differentiation. However, there was a significant depletion of late Mesp1 binding sites in 2i conditions. There was a strong correlation between the strength of Mesp1 binding and chromatin opening at these sites. Surprisingly, even when Mesp1 binding and chromatin remodeling are unaffected by 2i conditions, Mesp1 overexpression did not result in gene upregulation (Extended Data Fig. 5a-g). Altogether, these data reveal the importance of the cellular context in Mesp1 binding, chromatin remodeling and transcription regulation mediated by Mesp1.

Zic2 and Zic3 are enriched at Mesp1 bound enhancers

To uncover the TFs that cooperate with Mesp1 to regulate its binding, chromatin remodelling and regulation of target gene expression, we performed TF motif discovery at Mesp1 bound enhancers. The most enriched non-bHLH TF motif in Mesp1 ChIP-seq peaks was the ZIC TF motif (Fig. 3c). As ZIC3 loss of function mutations in mouse and human are associated with gastrulation and congenital heart defects³⁶⁻⁴¹, we hypothesized that Zic TFs could regulate Mesp1 transcriptional activity and the expression of its downstream direct target genes. Zic2, the closest paralog of Zic3, is also broadly expressed during gastrulation⁴² and was recently shown to promote CP specification and differentiation in human PSCs *in vitro*⁴³.

qRT-PCR and western blot showed that *Zic2* and *Zic3* are expressed during PSC differentiation *in vitro*, at the same time as *Mesp1* (Fig. 5a, Extended Data Fig. 6a). Single-molecule RNA fluorescent *in situ* hybridization (smRNA-FISH) in gastrulating mouse embryos showed that *Zic2* and *Zic3* were both co-expressed with *Mesp1* in the prospective cardiogenic mesoderm at E6.75 (mid-streak stage) and E7.25 (early bud stage). At E7.25, *Zic2* was more expressed in the anterior side of the embryo whereas *Zic3* was more abundant in the primitive streak (Fig 5b).

To validate our bioinformatic prediction that *Mesp1*, *Zic2* and *Zic3* are binding to *Mesp1*-bound enhancers, we performed ChIP-seq of endogenous *Zic2* and *Zic3* proteins in the absence of *Mesp1* expression (at day 2.5 of differentiation), at the onset of endogenous *Mesp1* expression and 24 hours following *Mesp1* overexpression (Fig. 5c). The high quality and specificity of the peaks were attested by strong enrichment of *Zic* motifs in these peaks (Extended Data Fig. 6b). *Zic2* and *Zic3* bound a significant fraction of *Mesp1*-bound enhancers (19% for *Zic2* and 29% for *Zic3*), in good accordance with the bioinformatic prediction (Figure 5d-e). Out of these, 95% of *Mesp1* peaks bound by *Zic2* were also bound by *Zic3* (Extended Data Fig. 6c). 153/577 (26%) of *Mesp1*/*Zic3* co-bound peaks were already bound by *Zic3* before *Mesp1* expression (day 2.5) and were also present at day 3.5 irrespective of *Mesp1* overexpression (group 1). In group 1, 127/153 (83%) of *Zic3*/*Mesp1* co-binding sites have their chromatin opened before *Mesp1* binding (primed peaks) whereas the other 17% had their chromatin opened following *Mesp1* overexpression (Fig. 5d-e, Extended Data Fig. 6d). 79/577 (14%) of *Mesp1*/*Zic3* co-bound peaks were bound by *Zic3* at day 3.5 at the beginning of endogenous *Mesp1* expression, without being associated with chromatin opening. Following *Mesp1* overexpression, these chromatin regions were strongly opened (group 2). Finally, 345/577 (60%) of *Mesp1*/*Zic3* co-bound peaks were bound by *Zic3* and presented chromatin opening only following *Mesp1* overexpression (group 3) (Extended Data Fig. 6d). Altogether,

these data show the temporality and dynamic nature of the distinct groups of Mesp1 and Zic3 co-binding sites and their impact on chromatin remodeling.

The binding of Zic2, Zic3 and Mesp1 to the same enhancers suggests that Mesp1 and Zic2/3 may physically interact. To assess this possibility, we performed co-immunoprecipitation using antibodies against endogenous Zic2 and Zic3 proteins, followed by western blot revealing the presence of Mesp1-3HA protein. We found that both Zic2 and Zic3 physically interact at the protein level with Mesp1 (Fig. 5f).

Zic3 regulates Mesp1 transcriptional activity at a subset of mesodermal enhancers

To assess whether Zic2 and Zic3 regulate Mesp1 function, we deleted *Zic2* or *Zic3* using CRISPR-Cas9 in PSCs allowing dox-induced Mesp1 overexpression in the context of Zic2 or Zic3 KO. Although Zic2 and Zic3 have been proposed to regulate pluripotency^{44,45}, we did not find changes in the expression of core pluripotency TFs when culturing *Zic2* and *Zic3* KO PSCs in Lif+2i medium (Extended Data Fig. 7a). We then assessed whether *Zic2* or *Zic3* deletion affects CP specification and differentiation during PSC differentiation *in vitro*. Mesp1 CPs are characterized by co-expression of Flk1 and PDGFRa *in vitro* and *in vivo*^{11,13,33,34}. Upon Mesp1 overexpression, the number of Flk1⁺/PDGFRa⁺ CPs was slightly decreased in *Zic2* and *Zic3* KO PSCs at day 4 and in *Zic3* KO PSCs day 5 (Fig. 6a). These data suggest a role for Zic3 in CP specification. We then assessed the impact of *Zic2* and *Zic3* KO on cardiac differentiation. Following Mesp1 overexpression, the number of CMs was slightly decreased *Zic3* KO cell lines, but no significant difference was found in *Zic2* KO cells (Fig. 6b, Extended Data Fig. 7b).

To unravel the mechanisms by which Zic TFs regulate Mesp1 transcriptional activity, we performed RNA-seq on *Zic2* and *Zic3* KO cells 24 hours after Mesp1 overexpression. Single *Zic2* KO cells only presented 11 significantly differentially expressed genes following Mesp1 expression compared to WT cells. In contrast, 15% (87/588) of direct upregulated Mesp1 target

genes were significantly downregulated in *Zic3* KO cells following *Mesp1* overexpression, including several genes known to be important for specification of the different heart lineages (e.g. *Aldh1a2*, *Hoxb1*, *Aplnr*, *Tenm4*)⁴⁶⁻⁵¹ (Fig. 6c-e). Moreover, several genes controlling pluripotency and other cell lineages (e.g. *Nodal*, *Nanog*, *Sox2*, *Foxa2*) were upregulated in *Zic3* KO cells (Extended Data Fig. 7c). These data show that *Zic3* alone regulates the expression of some of *Mesp1* target genes.

***Mesp1* and *Zic3* co-regulate gene expression during mouse gastrulation**

To assess the *in vivo* relevance of the cooperation between *Mesp1* and *Zic3* in regulating chromatin remodelling, enhancer activity and gene expression during CP specification, we investigated the expression of selected *Mesp1* and *Zic3* direct target genes *in vivo* in *Mesp1* and *Zic3* KO embryos. Among these genes, we selected a pan-marker of CPs, *Aplnr*⁴⁹⁻⁵¹ as well as *Alhd1a2* and *Hoxb1*, two known markers of the posterior SHF, a subpopulation of CPs that specifically contributes to the outflow region, atria and venous pole of the heart^{3,47,48}. *Aldh1a2* and *Hoxb1* correspond to late *Mesp1* target genes and *Aplnr* is an early upregulated *Mesp1* target gene. smRNA-FISH of these three genes in WT embryos at E7.25 demonstrated that they co-localize with *Mesp1* within the mesodermal cells leaving the primitive streak and migrating towards the anterior pole of the embryo (Fig. 6f-h). In *Mesp1*-null embryos, the expression of these genes was strongly downregulated (Fig. 6i-k), showing that they are *bona fide* *Mesp1* target genes *in vivo*.

To assess whether *Zic3* also controls the expression of these genes *in vivo*, we examined their expression on gastrulating *Zic3*-null embryos. To this end, we generated *Zic3* KO mouse lines with CRISPR/Cas9 by injecting Cas9 protein and guideRNA directly into zygotes (Extended Data Fig. 8a). We obtained several founders with either big deletions or insertions, thereby disrupting the *Zic3* gene within its first exon, upstream of the DNA-binding domain

coding sequence. The phenotypes of these novel *Zic3* KO alleles were identical to the previously reported *Zic3* null mice, with defects similar to the human phenotype associated with ZIC3 mutations including heterotaxy and exencephaly in a fraction of the *Zic3* mutant mice^{39-41, 52}. Closer phenotypic analysis showed that *Zic3* KO embryos present persistent truncus arteriosus (1/32), situs inversus (2/32), hypoplasia of the right ventricle (5/32). Moreover, *Zic3* KO embryos showed a thinner compact myocardial layer at E14.5, in good accordance with the decrease in CM differentiation found in *Zic3* KO PSCs. On the other hand, the endocardial layer was unaffected in *Zic3* KO hearts (Extended Data Fig. 8b-f). smRNA-FISH of *Hoxb1*, *Aldh1a2* and *Aplnr* in *Zic3* KO embryos showed that these genes were downregulated during gastrulation in *Zic3* KO embryos (4/5 for *Hoxb1*, 5/8 for *Aldh1a2* and 9/11 for *Aplnr*) (Fig. 6l-n). These data demonstrate that *Mesp1* and *Zic3* co-regulate the expression of key cardiac genes *in vivo* during mouse gastrulation.

***Zic3* and *Zic2* co-regulate *Mesp1* functions at mesodermal enhancers**

As *Zic2* binds a large fraction of *Mesp1*/*Zic3* bound enhancers, we assessed whether *Zic2* could compensate for the loss of *Zic3* during *Mesp1*-induced CP specification and differentiation from PSCs *in vitro*. To this end, we generated *Zic2/3* double KO (dKO) cell lines in *Mesp1*-inducible PSCs. Western blot showed the absence of *Zic2* and *Zic3* protein expression in this KO cell line (Extended Data Fig. 6a). These cells were able to grow in 2i+Lif medium and sustain the expression of core pluripotency TFs (Extended Data Fig. 9a). The specification of Flk1⁺/PDGFRa⁺ CPs and their terminal differentiation into CMs was completely suppressed in *Zic2/3* dKO PSCs (Fig. 7a-b and Extended Data Fig. 9b).

To define which *Mesp1* target genes and enhancers are co-regulated by *Mesp1* and *Zic2/3*, we performed RNA-seq on *Zic2/3* dKO cells 24 hours after *Mesp1* induction. Strikingly, 53% (310/588) of all up-regulated *Mesp1* direct target genes and 49% (675/1368) of direct and

indirect *Mesp1* up-regulated genes were strongly downregulated following *Mesp1* overexpression in *Zic2/3* dKO cells, including many genes that are essential for the specification and differentiation of cardiovascular lineages (Fig. 7c-f). Among the genes whose enhancers are co-bound by *Mesp1* and *Zic3*, 199/319 (62%) presented a decrease in their expression following *Zic2/3* dKO, further demonstrating the functional importance of *Zic2/3* in transcriptional regulation mediated by *Mesp1*.

We then assessed whether the major transcriptional defects after *Mesp1* induction in *Zic2/3* dKO cells are caused by loss of *Mesp1* binding to its enhancers (Fig. 7g-h). *Mesp1* ChIP-seq in *Zic2/3* dKO cells showed that *Mesp1* binding was decreased at 83% *Mesp1* binding sites, enriched for the late *Mesp1*-binding peaks (Fig. 7g, Extended Data fig. 9c, d).

Chromatin profiling of *Zic2/3* dKO PSCs following *Mesp1* overexpression by ATAC-seq revealed a major defect of *Mesp1*-induced chromatin remodelling, with the signal of 56% (2130/3839) of the enhancers remodelled following *Mesp1* overexpression and 48% of *Mesp1*-bound enhancers being strongly decreased (Fig. 7g-h, Extended Data Fig. 9e). Many of these enhancers were still bound by *Mesp1* in the absence of *Zic2/3*, but their chromatin regions were not anymore opened by *Mesp1* binding (group 3), showing that *Zic2/3* are important for regulating chromatin opening mediated by *Mesp1*. Motif discovery on the downregulated 3558 ATAC-seq peaks in *Zic2/3* dKO cells revealed a strong enrichment of the *Mesp1* motif, as well as *Gata* and *Zic* motifs (Extended Data Fig 9f).

To assess the cell-autonomous role of *Zic2* and *Zic3* in the regulation of *Mesp1* mesoderm specification *in vivo*, we performed CRISPR/Cas9 deletion of *Zic2* and *Zic3* in Tomato-expressing PSCs, then injected these cells in WT embryos of the same genetic background, and analysed the chimeric embryos when the heart is formed, at E9.5 (Fig. 7i). Out of two litters of E9.5 chimeric embryos, we analysed 3 embryos with a significant percentage

of chimerism. The contribution of WT tdTomato⁺ cells in similar chimeric experiments to the different embryonic lineages showed no difference in their differentiation potential compared to WT cells^{53, 54}. In chimeric embryos with *Zic2/3* double KO (tomato positive) that presented at least 5% of Tomato⁺ cells, we found a decreased contribution of tdTomato⁺/*Zic2/3* double KO cells to the heart. While the chimerism of TdTomato⁺ cells in the embryo are 5.2 \pm 0.3%, only 1.4 \pm 0.6% of tdTomato⁺ cells are found in cardiomyocytes, showing a significant decrease of *Zic2/3* double KO cells in cardiomyocytes. The contribution to the endocardium was more variable, precluding to draw strong conclusions due to the low number of chimeric mice analysed (Fig 7i-k). These data further support a role of *Zic2/3* during specification of cardiac progenitors and cardiomyocyte differentiation. Altogether, these data indicate that *Zic2* and *Zic3* act redundantly to regulate *Mesp1* binding and *Mesp1*-induced chromatin remodelling, which are crucial for cardiac progenitor specification and differentiation.

Discussion

During mouse gastrulation, cells transit from a pluripotent state to a lineage committed state within 24 hours. The dramatic changes in gene expression accompanying these cell fate transitions are mediated by rapid and precise coordinated action of multiple TFs. *Mesp1* acts as a master regulator of the specification and differentiation of cardiovascular lineages during embryonic development. By using *Mesp1* ChIP-seq, H3K27Ac and H3K4me1 ChIP-seq, ATAC-seq and RNA-seq, we demonstrated that *Mesp1* induces rapid opening of initially closed chromatin regions within the regulatory elements of key cardiovascular genes, a defined characteristic of pioneer TFs^{24, 55-57}, which enables the recruitment other TFs and chromatin remodelling factors, leading to activation of gene expression⁵⁸. Beside few exceptions⁵⁹⁻⁶³, the co-factors that are required to regulate TF pioneer activity remain unknown.

Using bioinformatic predictions and functional validation by loss of function experiments *in vitro* and *in vivo*, we identified *Zic3* and *Zic2* as essential transcriptional cofactors that regulate *Mesp1* TF activity and the expression of 50% of its direct cardiovascular target genes. Although CRISPR/Cas9 deletion of *ZIC2* in human PSCs leads to defective CM differentiation, no heart anomalies are found in *Zic2* deficient mice except a flatter outflow tract⁴³. *ZIC3* deficiency causes X-linked heterotaxy, a syndrome in which organs present defects in their lateral positioning in both mouse and humans^{36, 37}. *Zic3* mutants present variable heart defects (about 50%) ranging from septal defects, conotruncal anomalies, and other outflow tract defects^{38, 41}. In addition to the heterotaxy syndrome, *Zic3* null embryos present other gastrulation defects, ranging from failure to gastrulate to excess of mesoderm formation or axis duplication⁴⁰. The reason for early gastrulation and LR asymmetry defects in *Zic3* KO remains unclear, as deletion of *Zic3* prior to gastrulation but not in CPs or in the node, cause heart malformations⁶⁴, suggesting that *Zic3*-associated defects are secondary to early anomalies occurring in the early stage of gastrulation. Our *Mesp1*, *Zic2* and *Zic3* ChIP-seq data

demonstrate that *Mesp1* and *Zic* TFs bind a common set of enhancers, many of which are in the regulatory regions of key genes of CP specification and differentiation.

Although the transcriptional activity of *Mesp1* was reduced at key genes in *Zic3* KO PSCs, it was rarely abolished, suggesting that other *Zic* TFs could partially compensate for the absence of *Zic3*. Consistent with a genetic compensation between *Zic2* and *Zic3* during mesoderm formation, deletion of both *Zic2* and *Zic3* in *Mesp1*-inducible PSCs completely abolished the specification and cardiac differentiation of CPs following *Mesp1* overexpression. RNA-seq, *Mesp1* ChIP-seq and ATAC-seq of these double KO cell lines demonstrate that *Mesp1* overexpression cannot anymore activate many of its key enhancers that regulate the expression of many essential cardiovascular genes in *Zic2/3* double mutants. These data demonstrate that *Zic3* and *Zic2* act redundantly and are essential for cardiac mesoderm formation by regulating the TF activity of *Mesp1*. Consistent with an early role of *Zic2/3* in regulating *Mesp1* mesoderm specification, our chimeric embryo experiments between WT and *Zic2/3* double KO show that cardiomyocytes were decreased in *Zic2/3* KO cells.

Mechanistically, *Zic2* and *Zic3* physically interact with *Mesp1*. *Zic2* and *Zic3* bind a significant number of *Mesp1* bound enhancers prior to *Mesp1* expression. In the absence of *Zic2/3*, *Mesp1* present a decrease in its binding affinity at 87% of its binding sites, showing that *Zic2/3* are required for *Mesp1* binding to a subset of its target genes. In addition, whereas *Mesp1* can bind some of its binding sites in the absence of *Zic2/3*, *Mesp1* cannot anymore open the chromatin regions and upregulate gene expression, showing that *Zic2/3* are important to regulate the pioneer activity of the transcriptional complex induced by *Mesp1*. *Zic2/3* are also recruited by *Mesp1* expression at 60% of *Zic/Mesp1* co-bound enhancers. Finally, at a minor proportion of *Mesp1* binding sites, *Zic2/3* do not control *Mesp1* binding and chromatin opening but promote transcriptional activation, illustrating the different mechanisms by which *Zic2/3* control the transcriptional activity of *Mesp1*. Our data uncover a novel role of *Zic2/3* in

regulating Mesp1 functions by dynamically controlling Mesp1 binding to its direct target genes, its ability to open the chromatin at key mesodermal enhancers and the timing of Mesp1 transcriptional regulation. Further studies will be important to define whether other TFs or chromatin regulators cooperate with Mesp1 to control cardiac mesoderm specification and differentiation and to assess whether Zic TFs also control the transcriptional activity of other master lineage-specific TFs during development.

Author Contributions Statement

X.L., B.S., F.L. and C.B. designed the experiments, performed data analysis and wrote the manuscript. X.L. and B.S. performed most of the biological experiments. B.S. performed bioinformatic analysis for all the sequencing data. C. D. performed FACS. E.P. and F.L. performed the immunofluorescence and RNAscope experiments on mouse embryos. Y.A. generated the *Zic3* KO mouse lines. B.S., S.Z., E.B. and F.L. described and analyzed the *Zic3* mutant phenotypes. Chimeric embryos were generated by C. G., M-L. T., W. M. and processed analyzed by F.L. and B.G. Knockout cell lines for the chimeric embryos were generated by B.S. and C.G. C.P. provided technical support. E.C. and F.F. provided help for some NGS sequencing. S.G. and J.C.M. performed scRNA analysis in the initial submission. All authors read and approved the final manuscript.

Competing Interests Statement

The authors declare no competing interests.

Figure Legends

Figure 1: Dynamics of gene expression induced by Mesp1

a, Experimental scheme of the genetically engineered PSCs allowing temporally controlled Mesp1 induction (top) and the timing of RNA-seq, ChIP-seq and ATAC-seq analyses during differentiation of these PSCs using the hanging drop method *in vitro*. **b**, Expression pattern of genes that are regulated by Mesp1, representing 4 categories of target genes: early, constant, late upregulated and downregulated. Each sample was performed in two replicates. **c**, Normalized kinetics and average expression pattern for all genes within the 3 upregulated categories. Thin lines represent individual gene expression kinetics in dox (red) and no dox (blue) conditions, and thick lines represent the average profile of all genes within the category, separated by condition. **d**, Barplot illustrating the number of deregulated genes called using DESeq2 with a cut-off of 1.5-fold change expression and an adjusted p-value < 0.05 in each category⁶⁵, separated into genes that are upregulated or downregulated by Mesp1. n.s., non significant difference between the number of up- and downregulated genes. **e**, Representative expression of upregulated genes with different patterns of expression in Mesp1-expressing (GFP⁺) cells *in vivo*, which are either enriched at E6.75 (E6.75⁺⁺) or E7.25 (E7.25⁺⁺), or equally expressed in both populations (constant), as measured by microarray¹¹. **f**, Heatmap representing the *in vivo* patterns of expression of genes both upregulated by Mesp1 induction *in vitro* and in Mesp1-expressing cells *in vivo*, sorted according to the ratio of expression between E6.75 and E7.25 GFP⁺ cells. **g**, Barplot illustrating the correlation between early gene activation *in vitro* (yellow) and enrichment in Mesp1-expressing cells at the early time point (E6.75) *in vivo*, and between constant (green) and late (dark green) upregulated genes *in vitro* and genes enriched at the later time point (E7.25) *in vivo*. *** Significance was assessed by a chi-square test; the chi-square statistic is 36.7904. The p-value is < 0.00001. **h**, Gene set enrichment analysis (GSEA) showing the distribution of genes upregulated in GFP⁺ cells *in*

in vivo that are either more strongly expressed at E6.75 (enriched at E6.75) or at E7.25 (enriched at E7.25), within the ranking of all genes based on their expression at 12h dox versus 24h dox. Genes enriched at E6.75 are overrepresented in genes upregulated in 12h dox, whereas genes enriched at E7.25 are overrepresented in genes upregulated in 24h dox, demonstrating the parallel between PSC differentiation time *in vitro* and embryonic developmental time *in vivo*. Nominal p-value represents the statistical significance of the enrichment score, relative to a null distribution calculated through a permutation test.

Figure 2: Temporal control of chromatin remodelling by Mesp1

a, Mesp1 ChIP-seq 12 and 24 hours after dox addition at 2.5 days of EB differentiation, showing dynamic Mesp1 binding at the regulatory regions of two upregulated genes within 24 hours. Each replicate was performed twice. **b**, Expression dynamics of the corresponding early (*Fgf15*) and late (*Hoxb1*) Mesp1 direct upregulated genes. **c**, Barplot illustrating the number of Mesp1 direct target upregulated and downregulated genes within early, constant and late regulated genes, suggesting that Mesp1 functions predominantly as transcriptional activator. *** The proportion of up- and downregulated genes among all genes were compared as categorical variables, by a two-tailed Z-test, where $z=15.6501$ and $p < .00001$. **d**, Heatmap showing normalized signal in and around all 2011 Mesp1 ChIP-seq peaks 12 and 24 hours after dox. Peaks were separated into early, constant and late categories based on the ratio of normalized reads in these peaks between Mesp1 ChIP-seq at 12 and 24 hours. **e**, Barplot illustrating the number and proportion of early, constant and late regulated genes by Mesp1 (y axis) that can be found in the vicinity of early, constant and late Mesp1 ChIP-seq peaks (x axis), demonstrating the link between temporality of Mesp1 binding to DNA and its target gene expression. *** Significance was assessed by a chi-square test; the chi-square statistic is 66.48. The p-value is < 0.00001 . **f**, Representative example of the temporal remodelling of the chromatin associated with Mesp1 binding, as measured by ATAC-seq along with ChIP-seq for

Mesp1, lysine 27 acetylated histone 3 (H3K27Ac) and lysine 4 monomethylated histone 3 (H3K4me1), two markers of active enhancers and promoters. Mesp1 ChIP-seq and ATAC-seq samples were performed each twice; all other ChIP-seq were each performed once. **g**, Heatmap representing the signal for our ATAC-seq as well as H3K27Ac, H3K4me1 and Mesp1 ChIP-seq data within all Mesp1 binding sites, separated into *de novo* and primed peaks, depending on whether ATAC-seq signal was detected at 0 hours pre-Mesp1 binding (primed) or not (*de novo*). **h**, Quantification of overlap between Mesp1 ChIP-seq peaks and predicted nucleosome positioning in different ATAC-seq samples, as predicted by HMMR-ATAC⁶⁶. The peak can either be predicted to overlap with a nucleosome, be devoid of nucleosomes (open) or undefined (Undef). *** The chi-square statistic is 1328.6. The p-value is < 0.00001. **i**, Barplot illustrating the relationship between *de novo* opening of the chromatin and temporality of Mesp1 binding (x axis), demonstrating that early Mesp1 binding is more often associated with pre-opened chromatin (primed peaks). No peak (grey) represents Mesp1 binding sites where the ATAC-seq signal was undetectable in all conditions. *** Chi-squared test was used to assess the significance of this correlation. The chi-square statistic is 124.3. The p-value is < 0.00001.

Figure 3: Characterization of Mesp1-bound enhancers and prediction of putative transcriptional cofactors

a, Genomic regions containing the four Mesp1 ChIP-seq peaks that were deleted using CRISPR/Cas9, in the vicinity of Mesp1 upregulated target genes. **b**, RT-qPCR results where expression of Mesp1 target genes was quantified in WT and enhancer KO cell lines, with and without Mesp1 induction. Two-sided t-tests were used to compare values of expression in WT and KO cell lines. Horizontal line and error bar represent mean +/- standard error. n = 3 biologically independent experiments performed for two KO and one WT cell lines. **c**, Motif

enrichment analysis of all *Mesp1* ChIP-seq peaks, showing the highest enrichment of a particular bHLH motif (CAAATGG) as well as strong enrichment for other bHLH motifs, and other motifs corresponding to the binding sites of other families of TFs that regulate cardiovascular differentiation. Only motifs with $p < 10^{-10}$ and present in at least 10% of target peaks are shown. The CAAATGG motif was found by *de novo* motif discovery, whereas the other motifs were known TF binding sites within the Homer database²². p-values are calculated through a binomial test. **d**, Locus containing the *Pdgfra* proximal enhancer, which was either deleted or modified in different cell lines. For the enhancer modification, the only CCATTTG motif of this enhancer was replaced by a *NheI* restriction site (CGCTAGC) in order to readily identify cell lines containing one or two modified enhancers. **e**, Expression of *Pdgfra* by RT-qPCR in cell lines with homozygous WT, KO or mutated (Motif KO) *Mesp1*-bound proximal *Pdgfra* enhancer. Horizontal line and error bar represent mean +/- standard error. n = 3 biologically independent experiments performed for two KO and one WT cell lines for *Hoxb1* and *Hand1* enhancer KOs; n = 4 for two KO and two WT cell lines for *Myocd* enhancer KO. Quantitative qPCR data in WT and KO cell lines were compared by a two-sided t-test. **f**, Histogram of PDGFRa protein expression quantified by FACS at day 4 of differentiation in different cell lines, with *Mesp1* induction. **g**, Quantification of PDGFRa expression after *Mesp1* induction in WT, KO and mutated enhancer cell lines. Horizontal line and error bar represent mean +/- standard error. n = 5 biologically independent experiments performed for two KO and one WT cell lines. Two-sided t-test was used to compare the values of geometric mean fluorescence. **h**, Expression values of TFs that have their motif enriched in either *Mesp1* ChIP-seq peaks or ATAC-seq peaks that are opened by *Mesp1* without being directly bound by *Mesp1*, as illustrated in Extended Data Fig. 3d. n = 2 biologically independent experiments.

Figure 4. Validation of *Mesp1* target genes and enhancer remodeling in the presence of endogenous *Mesp1*

a, FACS plot used to isolate Flk1⁺/Pdgfra⁺ (Mesp1 expressing cells) and Flk1⁻/Pdgfra⁻ cells at day 4 of PSC differentiation in the absence of Mesp1 overexpression. RNA-seq and ATAC-seq experiments were performed in triplicates in these two populations. **b**, Examples of Mesp1 target genes with strong enrichment of their expression in Flk1⁺/Pdgfra⁺ versus Flk1⁻/Pdgfra⁻ cells (n=3 independent biological experiments). Error bars represent SEM. **c**, Quantification of the number of Mesp1 upregulated and downregulated genes that are significantly enriched or depleted in Flk1⁺/Pdgfra⁺ versus Flk1⁻/Pdgfra⁻ cells. *** Two-tailed Z-test statistic=13.007, p <0 .00001. **d**, Gene set enrichment analysis illustrating the enrichment of the Mesp1 upregulated genes in Flk1⁺/Pdgfra⁺ cells, and of Mesp1 downregulated genes in Flk1⁻/Pdgfra⁻ cells. Nominal p-value represents the statistical significance of the enrichment score, relative to a null distribution calculated through a permutation test. **e**, Representative locus showing the opening of Mesp1-bound enhancers in Flk1⁺/Pdgfra⁺ and closed in Flk1⁻/Pdgfra⁻ cells at day 4 of differentiation. **f**, Quantification of the number of Mesp1 ChIP-seq peaks, as well as peaks that are selectively opened (UP) or closed (DOWN) after Mesp1 induction, within peaks enriched in Flk1⁺/Pdgfra⁺ of Flk1⁻/Pdgfra⁻ populations. *** A two-tailed z-test was performed for all 3 comparisons, and all 3 were significantly different between peaks UP and DOWN in Flk1⁺/Pdgfra⁺ cells, with p<0.00001 and respectively z = 20.2 (Mesp1 ChIP-seq), 39.6 (ATAC-seq UP), and -28.5 (ATAC-seq DOWN). **g**, Heatmaps illustrating peaks that are both enriched or depleted in Flk1⁺/Pdgfra⁺ cells and upon Mesp1 overexpression. **h**, Motif enrichment analysis on peaks enriched in Flk1⁺/Pdgfra⁺ cells, showing the strong enrichment of Mesp1 binding sites and binding sites of other cardiovascular TFs. p-values are calculated through a binomial test²².

Figure 5: Zic2 and Zic3 bind to a fraction of Mesp1 binding sites

a, Expression profiles of *Mesp1*, *Zic2* and *Zic3* throughout differentiation of PSCs *in vitro* as measured by qRT-PCR. **b**, Single molecule RNA Fluorescent ISH (smRNA-FISH) of *Zic3* and

Zic2 together with *Mesp1* in transversal sections of gastrulating embryos *in vivo* at E6.75 and E7.25. epi, epiblast; PS, primitive streak; A, anterior; P, posterior. Dotted lines indicate *Mesp1* expression domains. * indicates background fluorescence found in the decidua and that differs from signal found in the embryo. n>3 independent embryos. **c**, Heatmap representing the signal of *Mesp1*, *Zic2* and *Zic3* ChIP-seq at different times within *Mesp1*-bound enhancers, demonstrating the co-occurrence of *Zic2* and *Zic3* as well as increasing signal as developmental time progresses. Each *Mesp1* and *Zic3* ChIP-seq sample was performed in duplicate; the three different *Zic2* ChIP-seq were performed in triplicate. **d**, Barplot representing the dynamic binding of *Zic2* and *Zic3* within *Mesp1*-bound enhancers, separated in primed versus *de novo* peaks based on ATAC-seq data presented in Fig. 2. **e**, Representative examples of enhancers co-occupied by *Mesp1*, *Zic2* and *Zic3*, illustrating the diversity of dynamic binding of *Zic2* and *Zic3* within *Mesp1* ChIP-seq peaks. **f**, Co-immunoprecipitation by using anti-*Zic2*, *Zic3* or IgG control antibodies, followed by Western blot of anti-HA antibody revealing the presence of *Mesp1*-3HA protein within each fraction. (n=3 independent experiments).

Figure 6: *Mesp1* and *Zic3* co-regulate gene expression during mouse gastrulation

a, Graph showing the number of Flk1/PDGFR α double positive cardiac progenitors in *Mesp1*-inducible wildtype (*Mesp1*), *Zic2* (*Mesp1/Zic2KO*) and *Zic3* KO (*Mesp1/Zic3KO*) cell lines at day 4 and day 5 of PSC differentiation (in at least 4 independent experiment), with *Mesp1* overexpression (mean with standard error of mean (SEM), unpaired two-sided t test p<0.0001). **b**, Proportion of Troponin-positive cardiomyocytes in *Mesp1*-inducible wildtype (*Mesp1*), *Zic2* (*Mesp1/Zic2KO*) and *Zic3* KO (*Mesp1/Zic3KO*) cells at day 10 of differentiation, after *Mesp1* overexpression (n=12 WT, n=14 *Zic2* KO and n=20 *Zic3* KO independent experiments, mean with SEM, unpaired two-sided t test p<0.0001). **c**, Heatmap of the expression of all *Mesp1* upregulated genes in *Zic2*, *Zic3* KO and WT cell lines. Each column represents one sample. **d**, Illustration of direct *Mesp1* upregulated genes that are downregulated in *Zic3* KO cell lines, as

measured by RNA-seq. (on at least 2 independent experiments). **e**, Barplot illustrating the proportion of genes regulated by *Mesp1* that are up- or downregulated in *Zic3* KO cell lines, using DESeq2 with cut-off values of 2-fold change and $p_{\text{adj}} < 0.05$ ⁶⁵. ** two-tailed Z-test with $z=3.0679$, $p=0.00214$. **f-n**, smRNA-FISH of *Mesp1* and *Aplnr*, *Hoxb1* or *Aldh1a2*, as direct *Mesp1* and *Zic3* direct target genes, in E7.5 embryos (representative of $n>4$ embryos per genotypes from different litters). The co-expression of *Mesp1* with *Aplnr* (**f-f'**), *Hoxb1* (**g-g''**) or *Aldh1a2* (**h-h'''**) was addressed in wild-type embryos on sections (f, g, h (Scale bars= 50 μ m) - higher magnifications are found in f', g' and h') and in whole mount (f'', g'', h'' – Scale bars= 200 μ m). **i-n**, Expression of *Aplnr*, *Hoxb1* or *Aldh1a2* in *Mesp1* KO (i-k) and *Zic3* KO embryos (l-n) at E7.5 at the late streak (LS) stage or no bud stage (OB). Decreased *Aplnr* expression was found in $n=6/6$ *Mesp1* KO embryos (i) and in $9/11$ *Zic3* KO embryos (l). Decreased *Hoxb1* expression was found in $n=4/4$ *Mesp1* KO embryos (j) and in $4/5$ *Zic3* KO embryos (m). For *Aldh1a2*, a decreased expression was observed in $n=4/4$ *Mesp1* KO embryos (k) and in $n=5/8$ *Zic3* KO embryos (n). A, anterior; P, posterior; epi, epiblast; EXE, extra-embryonic region; PS, primitive streak. Scale bars= 200 μ m.

Figure 7. *Zic3* and *Zic2* are essential regulators of *Mesp1* activity

a, Proportion of Flk1/PDGFR α double positive cardiac progenitors in *Mesp1*-inducible WT and *Zic2/Zic3* double KO (dKO) cells, as measured by FACS at day 4 of differentiation ($n=12$ WT, $n=12$ WT + dox, $n=8$ *Zic2/3* dKO and $n=8$ *Zic2/3* dKO + dox independent experiments, mean with SEM), Statical analysis was performed by unpaired student two-tailed t test. **b**, Proportion of Troponin T positive cardiomyocytes in *Mesp1*-inducible WT and *Zic2/Zic3* double KO cell lines at day 10 of differentiation, with and without induction of *Mesp1* ($n= 12$ independent experiments, mean with SEM). Statical analysis was performed by unpaired student t test. **c**, Heatmap of the expression values of all *Mesp1* upregulated genes in WT as well as single and double *Zic* KO cell lines. Each column represents one sample. **d**, Barplot illustrating the

proportion of genes regulated by *Mesp1* that are up- or downregulated in *Zic2/Zic3* dKO cell lines. *** $z=16.166$; $p < 0.00001$. **e**, Gene set enrichment analysis (GSEA) where genes were ranked based on fold-change expression between *Mesp1* WT and *Zic2/3* dKO cells 24h after dox induction (x axis). *Mesp1* direct upregulated targets were plotted (black lines) on these ranked list of genes, demonstrating the enrichment of these genes in downregulated genes in *Zic2/3* dKO cells. **f**, Examples of cardiac-related genes that are significantly downregulated in *Zic2/3* dKO cells 24 hours after *Mesp1* induction (mean with SEM). **g**, Heatmap of all *Mesp1* ChIP-seq peaks, showing the signal of *Mesp1* ChIP-seq performed in *Zic2/3* dKO cells, as well as ATAC-seq performed in WT and *Zic2/3* dKO cells after *Mesp1* induction. All samples collected in *Zic2/3* dKO cells were performed in triplicate. **A**, primed peaks with maintained *Mesp1* binding in *Zic2/3* dKO cells; **2**, de novo peaks with loss of *Mesp1* binding; **3**, primed peaks with loss of *Mesp1* binding in dKO cells; **4**, de novo peaks with sustained *Mesp1* binding but no chromatin opening. **h**, Illustrative examples of *Mesp1* binding sites where *Mesp1* is (or not) altered in *Zic2/3* dKO cells, and where chromatin opening upon *Mesp1* induction is severely reduced at these loci. **i**, Schematic overview of the experiment performed. *Zic2/3* dKO *tdTomato*-positive cells were injected into WT blastocysts of the same genetic background and collected at E9.5. **j**, smRNA-FISH on section of a E9.5 chimeric embryo showing *tdTomato* and *Tnnt2* expression (representative picture of a total of $n=3$ independent embryos). BA, branchial arch. Scale bar= 200 μ m. **j'** corresponds to higher magnification with a zoom on the cardiac region. Empty arrowheads show *Tnnt2* negative *Zic2/3* dKO *tdTomato*⁺ cells found in the heart, corresponding to endocardial cells **k**, Percentage of *Tomato*⁺ chimerism in the whole embryo (total), in cardiomyocytes (CM) and in non-cardiomyocytes heart cells (non-CM) as measured by the ratio between the area of *tdTomato*⁺ pixels and the area of DAPI staining nuclei ($n=10, 12$ and 13 slides examined over 3 biologically independent embryos, mean with SEM). Statistical analyses were performed by two-tail paired student *t* tests.

Extended Data Figure Legends

Extended Data Figure 1. Temporal regulation of gene expression mediated by homogeneous Mesp1 induction within embryoid bodies.

a, RNA-FISH on sections of EBs from Mesp1 Dox-inducible PSC lines in control conditions (NO DOX) or 24h after doxycycline induction (+DOX) showing *Mesp1* expression in red. (representative image of n=6 independent embryonic bodies). **b**, Percentage of cells that are positive for *Mesp1* using RNA in situ hybridization, in control (NO DOX) or upon Mesp1 overexpression (+DOX) (n= 6 NO DOX and n= 7 +DOX independent embryoid bodies). Error bars indicate SEM. Statistical analyses were performed by two-tail unpaired student *t* tests. $p= 2.53 \times 10^{-6}$ **c**, Level of *Mesp1* expression in control (NO DOX) or doxycycline conditions (+DOX) as measured by the signal intensity from the smRNA-FISH. Error bars indicate SEM. Statistical analyses were performed by two-tail unpaired student *t* tests. n= 30 representative Mesp1+ cells / condition. $p= 6.87 \times 10^{-10}$ **d**, Principal component analysis of RNA-seq samples performed at day 2.5 (0h), day 3 (12h following Mesp1 overexpression) and day 3.5 (24h following Mesp1 overexpression) in control (no dox) and Mesp1 overexpression (dox) conditions during PSC differentiation. Note the excellent concordance between biological duplicates. **e**, Representative examples of genes that undergo early, constant or late downregulation mediated by Mesp1. Examples were chosen to represent the diversity of kinetics we could find in genes repressed by Mesp1. **f**, Plots representing all genes classified as early, constant or late downregulated, as well as their respective average profile (thick lines).

Extended Data Figure 2. Temporal analysis of Mesp1 transcription factor activity.

a, Pie chart representing the distribution of the position of Mesp1 ChIP-seq peaks relative to protein-coding genes ($n = 2$ for each time point). **b-c**, Graph representing the dynamics of ATAC-seq (**b**) and H3K27Ac ChIP-seq (**c**) signal within early, constant and late Mesp1 ChIP-seq peaks. Average profiles are shown by the thick red (dox) and blue (no dox) lines. **d**, Dot plot illustrating the correlation between temporality of Mesp1 binding and surrounding H3K27Ac deposition (left), or Mesp1 binding and ATAC-seq opening of the chromatin (right). For each individual Mesp1 ChIP-seq peak, the average signal was measured for all three types of experiments at 12 hours and 24 hours dox, in order to extract a measure of fold-change between 12 and 24 hours. The \log_2 value of this fold-change for each peak was compared between each type of experiment. p-values were calculated through a two-tailed t-test.

Extended Data Figure 3. Motif discovery of enhancers activated by Mesp1.

a, Motif discovery performed separately in Mesp1 ChIP-seq peaks classified as early, constant or late peaks. p-values are calculated through a binomial test. **b**, Same pipeline as panel a but separating peaks as *de novo* versus primed Mesp1 peaks. Stars represent the enrichment of the CAAATGG motif in pioneer peaks in comparison to non-pioneer peaks through a two-tailed Z-test. **c**, Quantification of the occurrence of all forms of bHLH motifs in Mesp1 ChIP-seq peaks, showing the prevalence of CAAATG motif, most often with an extra G. *** The top 2 bHLH motifs were significantly overrepresented ($p < 0.00001$) through a two-tailed Z-test, with $z = 17.5$ for CAAATG and $z = 5.9$ for CAGATG. **d**, Representative genomic locus where ATAC-seq and H3K27Ac ChIP-seq peaks are upregulated 24h following Mesp1 expression but which are not directly bound by Mesp1 (red boxes), suggesting that their regulation is mediated by other TFs, whose expression is induced directly or indirectly by Mesp1.

Gata4 ChIP-seq data²⁷ (green) shows a strong overlap between these *de novo* opened peaks not bound but induced by Mesp1. **e**, Motif discovery searching for known TF binding sites within ATAC-seq peaks that get opened by Mesp1 but are not directly bound by Mesp1. p-values are calculated through a binomial test. **f**, Quantification of peaks containing a Gata4 motif, both in Mesp1 ChIP-seq peaks and ATAC-seq peaks UP without Mesp1 binding, separated as peaks actually bound by Gata4 or not bound by Gata4 using a published ChIP-seq dataset³³. *** Gata4 motifs are statistically significantly enriched in Gata4-binding peaks in Mesp1 ChIP-seq ($z=8.34$, $p<0.00001$) and in ATAC-seq peaks UP ($z=13.6$, $p<0.00001$). These values were calculated through a two-tailed Z-test.

Extended Data Figure 4. Repression of the core pluripotency network by Mesp1.

a, Representative genomic locus (*Cdh1*) where ATAC-seq and H3K27Ac ChIP peaks found in control (no dox) conditions are absent or smaller in dox conditions, without presenting any Mesp1 binding (blue boxes), suggesting indirect repression of chromatin opening by other factors. **b**, Motif discovery within peaks that are closed in dox conditions, including enrichment of a compound OCT-SOX-TCF-NANOG motif. p-values are calculated through a binomial test. **c**, Heatmap showing signal of ATAC-seq, H3K₂₇Ac ChIP-seq and published Nanog, Oct4 and Sox2 ChIP-seq data within peaks that were closed after dox-induced Mesp1 overexpression³². **d**, RNA-seq expression of core pluripotency transcription factors with and without Mesp1 overexpression.

Extended Data Figure 5. Context-dependency of Mesp1 activator potential

a, Heatmap of the expression values of Mesp1 upregulated genes in undifferentiated PSCs (2i conditions), with or without Mesp1 induction (dox). RNA-seq samples in 2i were performed twice. **b**, Overlap between genes directly and indirectly activated by Mesp1 during PSC differentiation or in 2i, illustrating the paucity of Mesp1-mediated gene activation in pluripotency. **c**, Heatmap illustrating Mesp1 binding affinity to its enhancers in 2i by Mesp1 ChIP-seq and the subsequent lack of chromatin opening by ATAC-seq in 2i conditions. Each row represents a Mesp1 binding site detected during differentiation at 24h dox. Peaks were ordered by unsupervised k-means clustering. 1, *de novo* peaks where Mesp1 binding and subsequent chromatin opening is lost in 2i; 2 and 2', primed peaks with conserved Mesp1 binding and chromatin opening in 2i; 3, *de novo* ATAC-seq peaks where Mesp1 binding and chromatin opening is conserved in 2i. All samples collected in 2i were performed twice. **d**, Representative examples of Mesp1 binding loci in 2i conditions. **e-f**, Classification of Mesp1 ChIP-seq peaks found in 2i into previously detailed chromatin opening (e) or kinetic (f) groups. *** Late peaks were significantly depleted in 2i conditions ($z=-7.86$, $p<0.00001$). These values were calculated through a two-tailed Z-test. **g**, Quantification of the correlation between Mesp1 binding strength measured by Mesp1 ChIP-seq and chromatin opening in ATAC-seq in 2i (24h dox), demonstrating a linear correlation between these two variables

Extended Data Figure 6. Zic2 and Zic3 cooperate with Mesp1 and potentially with other mesoderm-inducing TFs.

a, Western blot illustrating the expression of Zic2 and Zic3 with and without Mesp1 induction, at day 3.5 (24 hours) of PSC differentiation, as well as the lack of Zic2 and Zic3 protein expression in Zic2/3 double KO cell lines. (n=2 independent experiments)

b, Illustration of the two most enriched motifs in all *Zic2* and *Zic3* ChIP-seq detected peaks. p-values are calculated through a binomial test. **c**, Venn diagram illustrating the number of overlapping peaks between *Mesp1*, *Zic2* and *Zic3* ChIP-seq datasets. P-value was calculated using a hypergeometric test, using bedtools fisher⁸⁵. **d**, Illustration of the temporality of *Zic3* binding within primed and *de novo* *Mesp1*-bound peaks, with associated ATAC-seq signal. 1, peaks already bound by *Zic3* at day 2.5 (0 hours); 2, peaks bound by *Zic3* at 24h no dox; 3, peaks bound by *Zic3* at 24h dox. **e**, Barplot showing the proportion of *Mesp1*/*Zic3* co-bound peaks at different times during PSC differentiation, separated based on kinetics of *Mesp1* binding. *** The chi-square statistic is 29.27. The p-value is < 0.00001.

Extended Data Figure 7. *Zic2* and *Zic3* regulate *Mesp1*-induced CP specification and differentiation.

a, mRNA expression of the core pluripotency associated TFs in *Mesp1*-inducible WT, *Zic2* and *Zic3* KO PSCs in *Lif/2i* pluripotency conditions, as measured by RT-qPCR. Data is pooled from at least duplicate experiments on two independent KO clones. (n=2). Error bars indicate mean +/-SEM, statistical analysis was performed by 2-way ANOVA. **b**, Representative immunofluorescence for Troponin T in *Mesp1*-inducible WT, *Zic2* and *Zic3* KO cell lines at day 10 of differentiation, illustrating the ability of *Mesp1* overexpression to overcome cardiac differentiation defects in *Zic2* and *Zic3* KO cell lines. (n>6 independent experiments). Scale bars=100 μ m. **c**, Illustrative examples of genes that are significantly upregulated in *Zic3* KO cells in comparison to WT cells, including known important factors of pluripotency and endoderm differentiation.

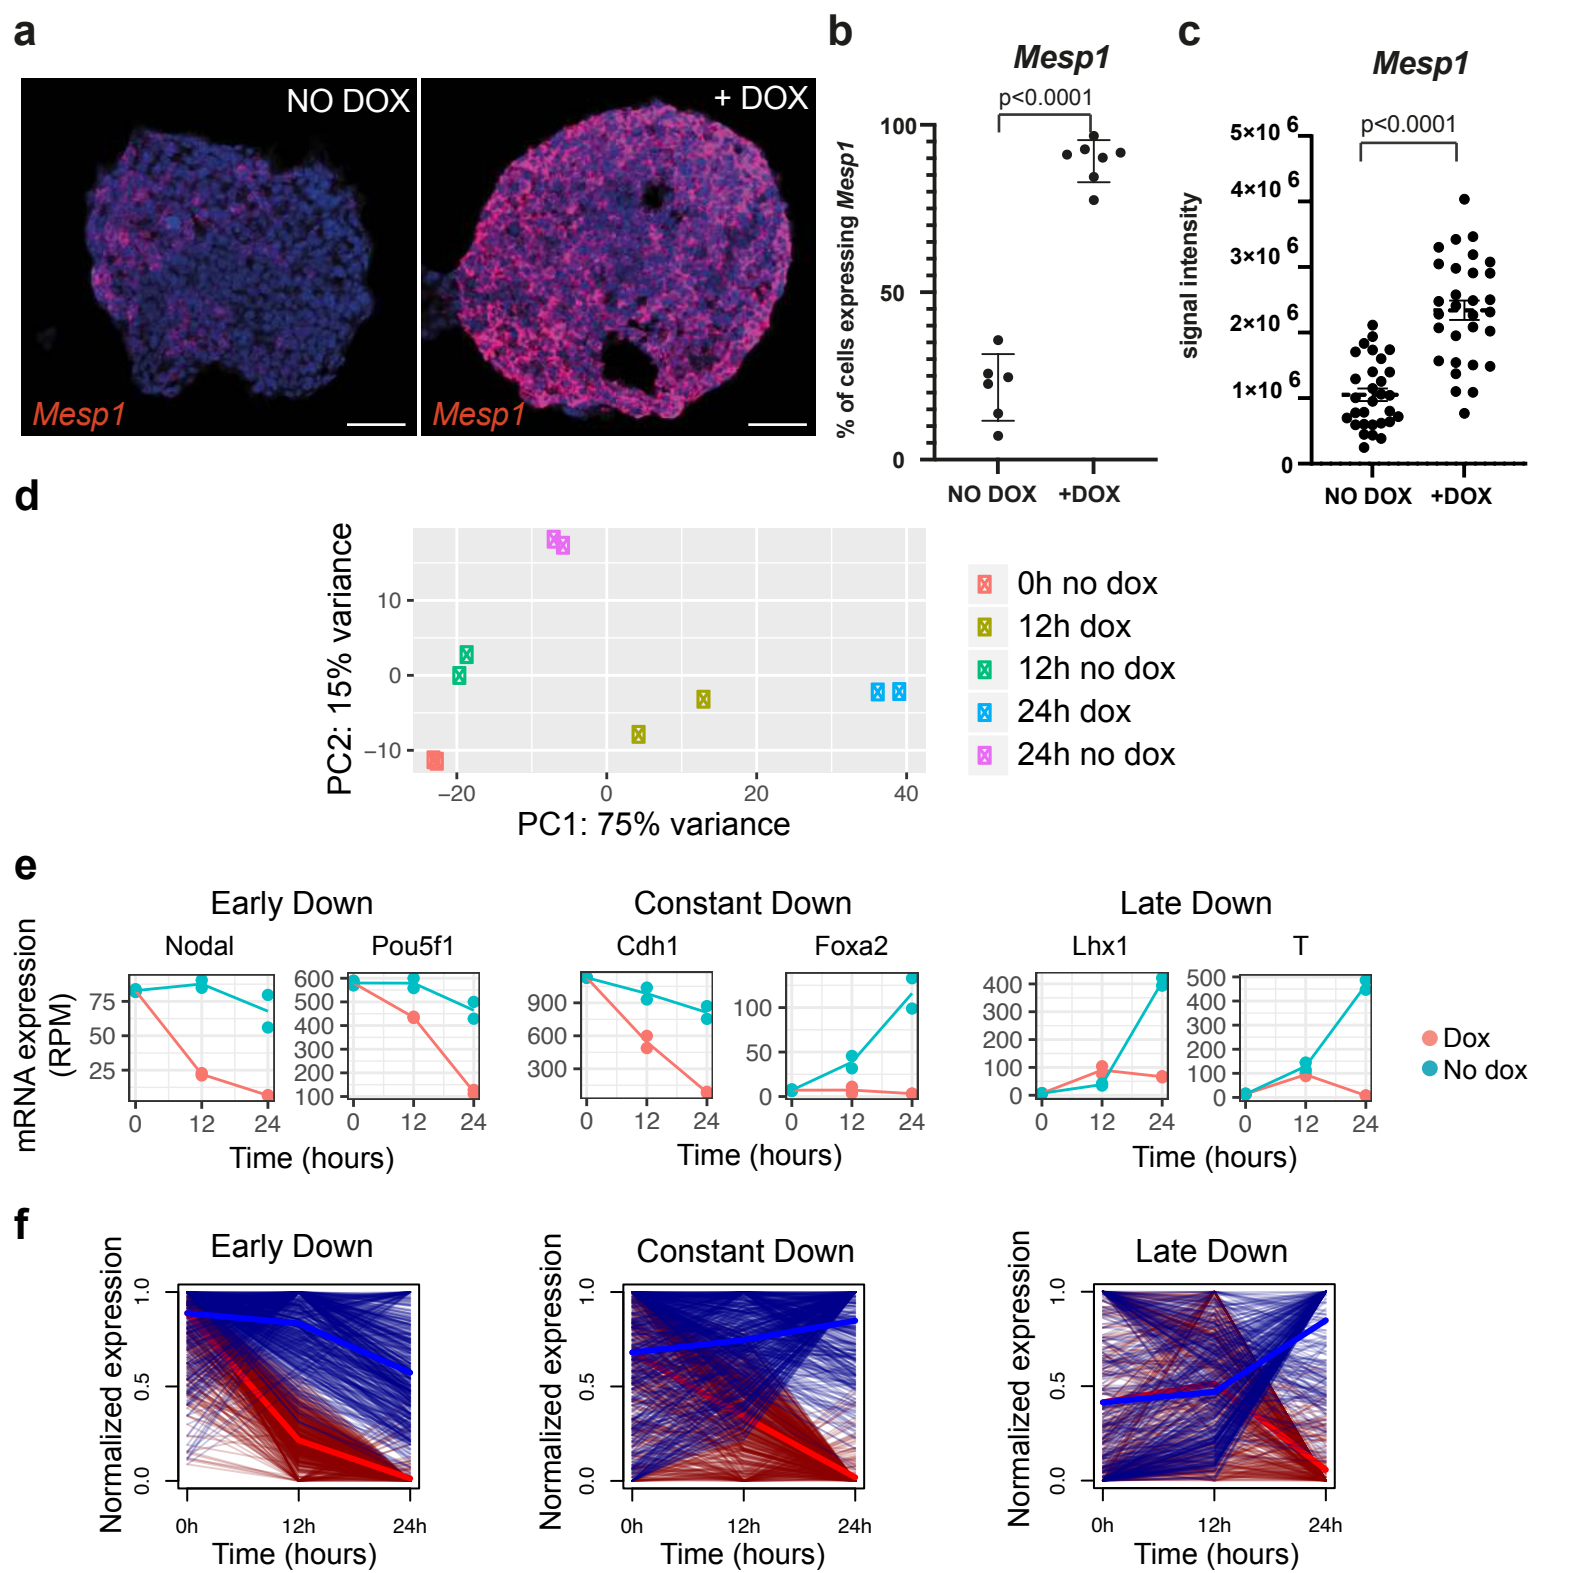

Extended Data Figure 8. Heart defects observed in the newly generated *Zic3* KO line.

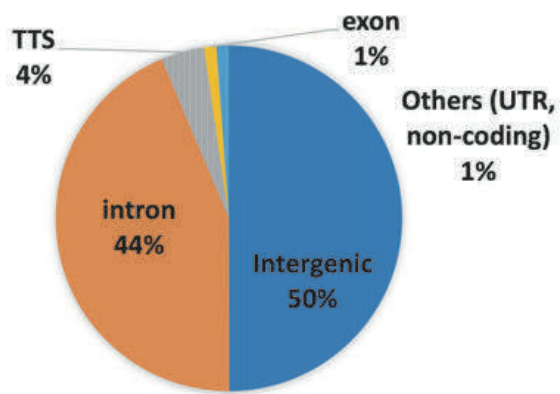

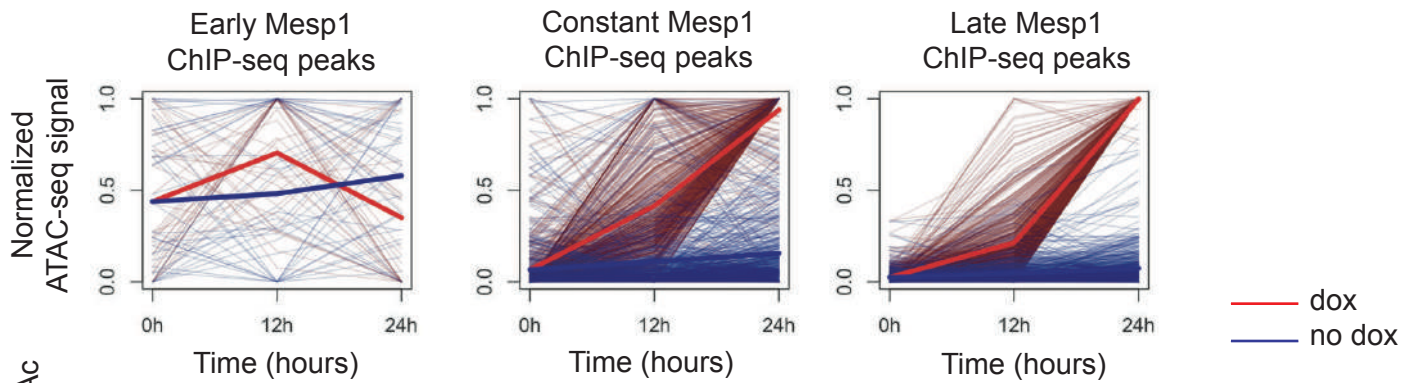

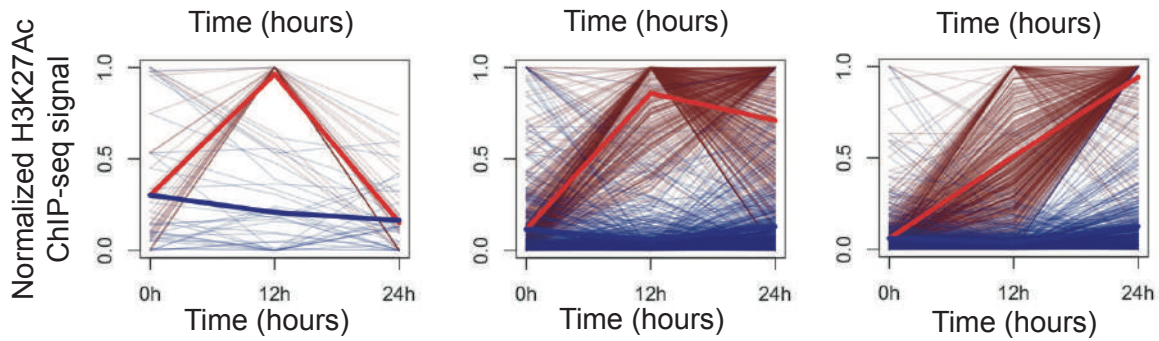

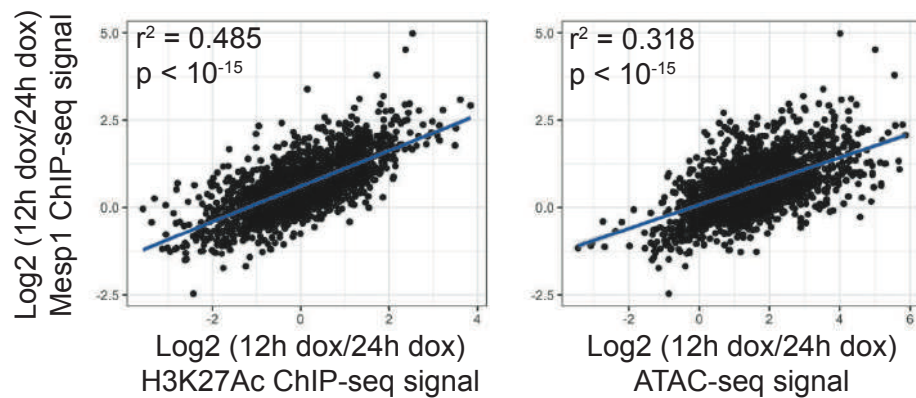

a, Zygote injection strategy used to generate *Zic3* KO mice. **b**, Pictures of Wild type (WT) and homozygous null (*Zic3*^{KO}) E14.5 embryos, showing severe neural tube closure defects and exencephaly found in a subset of *Zic3* KO embryos (n=10/32). Scale bars= 1mm. **c**, Range of cardiac morphological abnormalities found in *Zic3* KO embryos at E14.5. We observe outflow tract defects with persistent truncus arteriosus (PTA bottom left panel – n=1/32), hypoplasia of the right ventricle (RV) (upper right panel – n=5/32) and mutants with a *situs inversus* phenotype (bottom right panel – n=2/32). Scale bars= 1mm. **d**, ratio of the surface area of the right ventricle compared to the surface area of the left ventricle in wild type (black – n= 26) and *Zic3* KO (red – n=44). Error bars indicate mean +/-SEM. Unpaired, two-tailed t-test showed a p-value=0.0004. **e**, Mean thickness of the compact myocardial (CM) layer of the ventricles in wild type (black – n=6) and *Zic3* KO embryos (red – n=12). Error bars indicate mean +/-SEM. Unpaired, two-tailed t-test showed a p-value=0.0074. **f-f'**, Immunofluorescence on E14.5 wild type (**f**) and *Zic3* KO (**f'**) hearts using an anti-cardiac Troponin T (cTnT) antibody to label the cardiomyocytes and isolectinB4 to label the endocardium (representative pictures from n>4 independent hearts of each genotype). No endocardial defect was observed in *Zic3* KO embryos while the cTnT+ layer was thinner in **f'**. Scale bars= 200µm. RV, right ventricle; LV, left ventricle; RA, right atrium; LA, left atrium; pt, pulmonary trunk; ao, aorta.

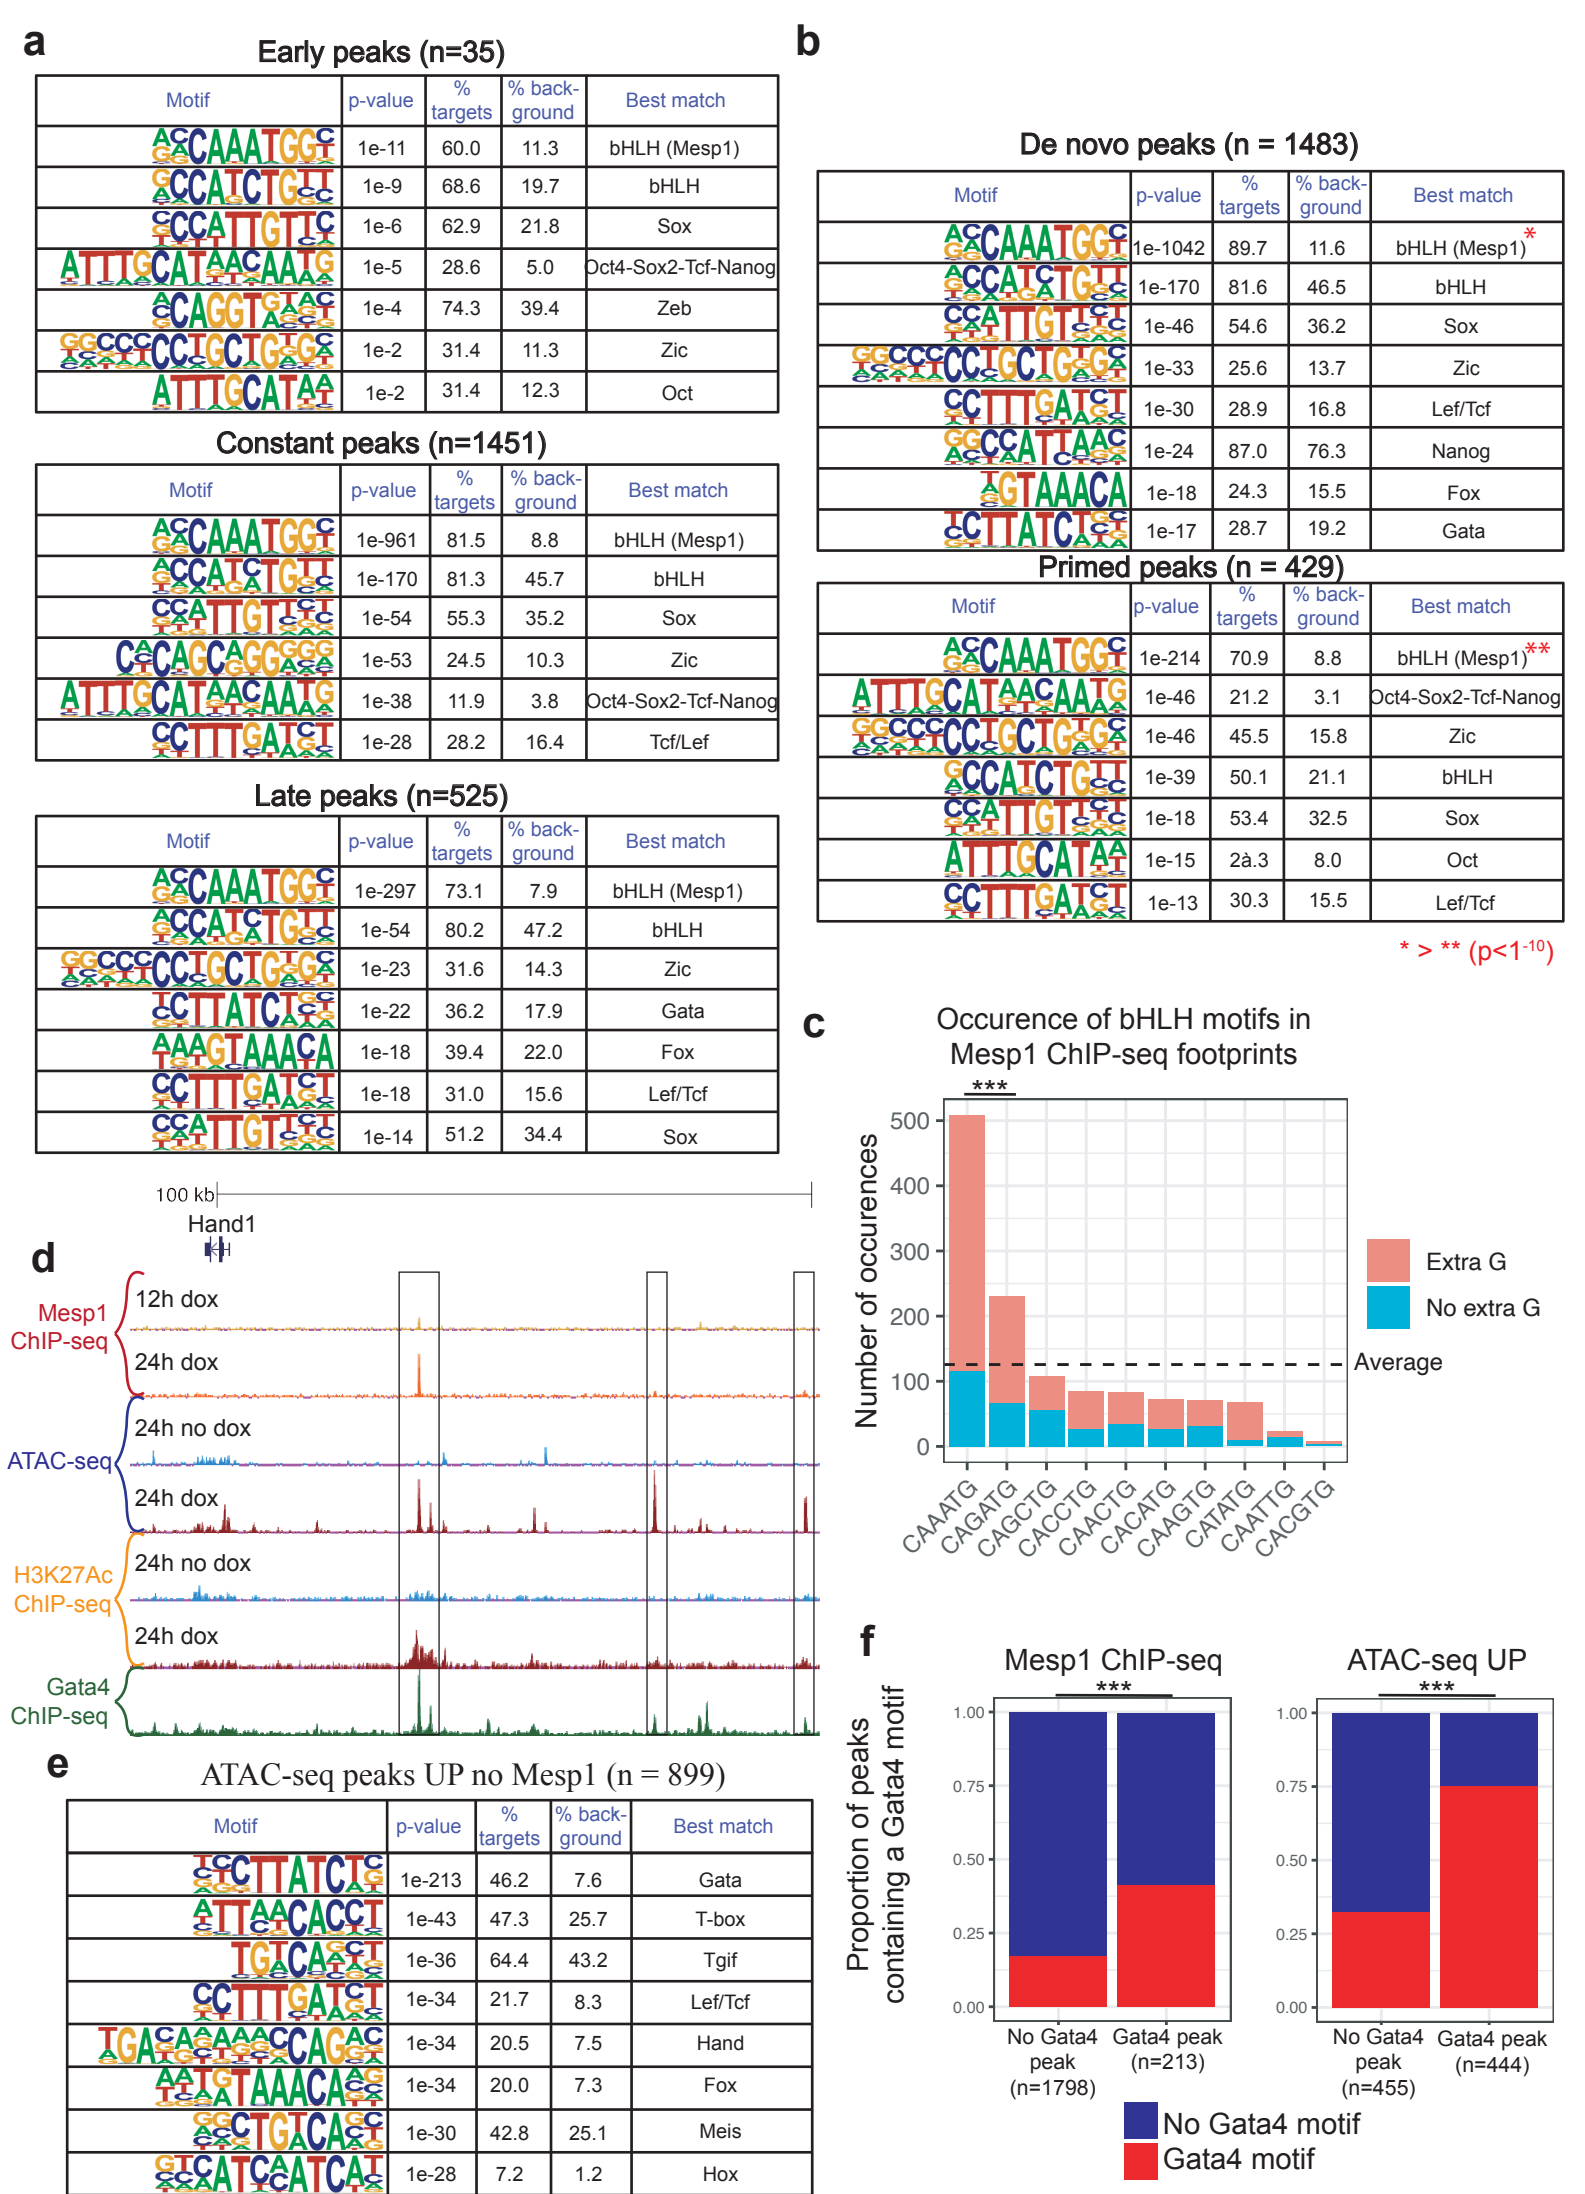

Extended Data Figure 9. *Zic2* and *Zic3* redundantly regulate *Mesp1* activity.

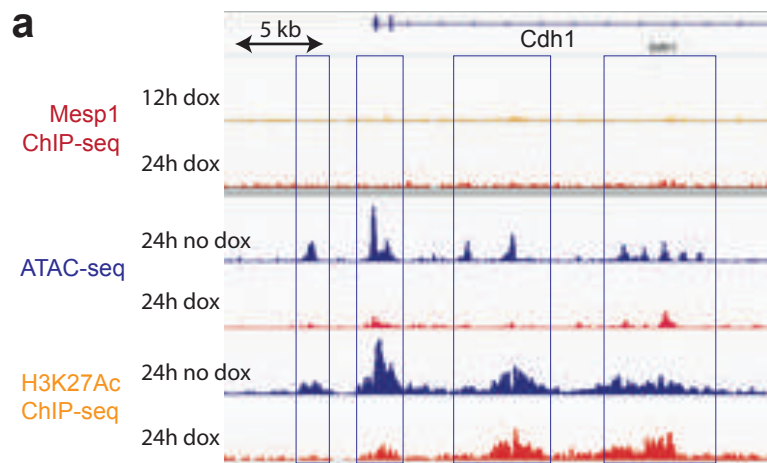

a, Expression of 3 core pluripotency genes in *Mesp1* WT and two independent *Zic2/3* KO PSC cell lines cultured in *Lif/2i* medium. Data from two independent experiments,

Error bars indicate mean \pm SEM, statistical analysis was performed by 2-way ANOVA. **b**, FACS profiles of EBs at day 4 of differentiation from *Mesp1* WT and *Zic2/3* dKO cell lines, illustrating the decrease in *Flk1* and *PDGFRa* expression in *Zic2/3* dKO cell lines both in no dox and dox conditions. **c**, Table showing the distribution of genes that were downregulated in *Zic3* KO and *Zic2/3* dKO cells within the temporal categories of *Mesp1* direct upregulated target genes. There was no particular enrichment for early, constant and late genes within the *Zic2/3*-dependent fraction of *Mesp1* target. **d**, Barplot illustrating the proportion of early, constant and late *Mesp1* binding sites within *Mesp1* ChIP-seq peaks conserved in *Zic2/3* dKO cell lines. *** for late genes, $z = -5.845$, $p < 0.00001$. These values were calculated through a two-tailed Z-test. **e**, Representation of the proportion of *Mesp1* ChIP-seq peaks as well as ATAC-seq peaks that are opened (UP) or closed (DOWN- upon *Mesp1* induction in WT cells which are preferentially closed in *Zic2/3* dKO cells after *Mesp1* induction. *** all three comparisons were significant with $p < 0.00001$ and respectively $z = 34.9$ (*Mesp1* ChIP-seq), $z = 54.2$ (ATAC-seq UP) and $z = -20.1$ (ATAC-seq DOWN). These values were calculated through a two-tailed Z-test. **f**, Motif enrichment analysis of ATAC-seq peaks that were preferentially closed in *Zic2/3* dKO cells in comparison to WT cells. p-values are calculated through a binomial test.

Methods

Tetracycline-inducible PSC lines

A *Mesp1*-3HA stable transgenic PSC line was generated as described previously ¹.

CRISPR/Cas9 Knockout PSCs

CRISPR/Cas9 knockout PSCs for *Zic2*, *Zic3*, and *Zic2/Zic3* together were generated following the protocol previously described ^{1,2}. Briefly, two pairs guide RNAs for each gene that target two regions of the gene separated from 364bp to 2381bp were designed using a CRISPR/Cas9 online tool (Benchling [Biology Software](2019-2020), retrieved from <https://benchling.com>; Supplementary Table 1) and the vectors pX330-U6-Chimeric_BB-CBh-hSpCas9 (PX330) and pSpCas9n (BB)-2AGFP (PX461) were obtained from Addgene (#42230 and #48140). The guide RNAs were cloned into a modified short version of PX330 in which the Cas9 cassette was removed. Four plasmids containing the guide RNAs for Single KO or eight Plasmids for double KO were co-transfected together with PX461 (Cas9n) into *Mesp1*-3HA PSCs using Lipofectamine 2000 (Thermofisher, 11661089), in order to generate a big deletion either upstream or encompassing the DNA-binding domain of the targeted gene(s). Transfected GFP-positive cells were FACS-sorted individually into 96-well plates 48 hours after transfection using a FACSAria (BD Biosciences). After 7 to 12 days, colonies were passaged and then screened by PCR using primers flanking the expected deletion site (Supplementary Table 2). *Zic2* and *Zic3* single and double KO clones were selected based on homozygous PCR profiles and confirmed by Sanger sequencing.

CRISPR/Cas9 enhancer knockout PSCs

The same strategy as above was used to generate enhancer KO cell lines. 8 gRNAs were inserted into the shortened version of PX330 in order to generate deletions between 200 and 480 base pairs, centred around a *Mesp1* ChIP-seq peak and encompassing the central bHLH motifs of

the peak (Supplementary Table 1). At least two independent clones per peak for five enhancers were generated, targeting enhancers for *Myocd*, *Pdgfra*, *Hoxb1* and *Hand1*.

Motif replacement in the *Pdgfra* proximal *Mesp1*-bound enhancer

Two guide RNAs overlapping with the targeted motif (CCATTTG) were separately cloned into PX330 containing wildtype Cas9 (Supplementary Table 1). Single strand DNA containing 40 bp homology arms on each side of the motif, which was modified into CGCTAGC, a *NheI* restriction site, was synthesized by Eurogentec. *Mesp1*-inducible PSCs were transfected with PX330 containing the gRNA and the ssDNA template, then FACS sorted into single cells based on GFP as above. Selection of clones was performed using PCR for amplification of the whole region, followed by *NheI* digestion. Homozygous and precise editing of the motif was validated by Sanger sequencing.

PSC Culture and Differentiation

Mesp1-3HA PSCs were cultured as previously described^{3,4}. After generating KO cell line by CRISPR/Cas9n, PSC cell lines were cultured on feeder free condition with LIF/2i medium (ES medium supplemented with 1 μ M PD0325901 (Sigma, PZ0162) and 3 μ M Chir99021 (Sigma, SML1046). Differentiation was performed in hanging drops as for *Mesp1*-3HA PSCs.

RT-qPCR during PSC differentiation

RT-qPCR were performed as described previously^{3,4}. qPCR primers were listed in supplemental table 3.

RNA sequencing

RNA extraction was performed by using Qiagen RNeasy Micro Kit according to the manufacturer's instructions. Before sequencing, quality of the RNA was evaluated using a Bioanalyzer 2100 (Agilent). Indexed cDNA libraries were obtained using Ovation Solo RNA-

seq Systems (NuGen) following the manufacturer's recommendations. The multiplexed libraries (11 pM/18 pM) were loaded onto flow cells and sequences were produced using a HiSeq PE Cluster Kit v4 and TruSeq SBS Kit v3-HS (250 cycles) on a HiSeq 1500 (Illumina).

ChIP Sequencing

ChIP was performed as described previously on Mesp1-3HA-flagged Dox-inducible PSC lines⁴. Briefly, EBs were collected at 12h and 24h after induction of dox (1mg/ml), fixed directly with 1% formaldehyde for 7 min at RT, and quenched with 0.125M glycine for 5 min. CHIP was performed according to the manufacturer's instructions (CHIP-IT express kit) with antibodies reported in Supplementary Table 4. 2-10 ng of pulled-down DNA was used to construct the sequencing library by using Truseq ChIP Library Preparation kit (Illumina) or NEB Next Ultra II DNA library Prep Kit for Illumina (NEB) according to manufacturer's instructions, and subsequently sequenced on a HiScanSQ module (Illumina).

ATAC Sequencing

ATAC-seq was performed following standard protocol⁵. Briefly, EBs were collected at the same time points and conditions than the RNA-seq datasets, rinsed with dPBS (ThermoFisher, 14190144) and dissociated with accutase (Sigma, A6964). 125,000 cells or FACS sorted cells were used to perform the ATAC-seq, and ATAC-seq library were performed according to manufacturer's instructions (Nextera DNA sample Preparation Kit, Illumina), and size selection from 200bp to 800bp was performed by Ampure XP beads (Beckman) before NGS sequencing.

Co-immunoprecipitation

Co-immunoprecipitation was performed according to a previously published protocol⁶. 3µg rabbit IgG control antibody, rabbit anti-Zic3 or rabbit anti-Zic2 (Supplementary Table 4) was added into same amount of protein (around 1mg in 300µl lysis) and rotated at 4 °C overnight,

followed by addition of Dynabeads™ Protein G (ThermoFisher Scientific, 10003D) at 4°C for 4 hours. Washes were performed with NETN buffer (20mM Tris (pH 8), 1mM EDTA, 900mM NaCl, 0.5% CA-630). 15µl eluted samples were used to perform the western blot by mouse anti-HA antibody (Supplementary Table 4).

Western blot

Western blots were performed as previously described¹. Antibodies were listed in Supplementary Table 4.

Flow Cytometry

Flow cytometry was performed as previously described³. Antibodies used are reported in Supplementary Table 4.

Immunofluorescence Analysis

Immunofluorescence on EBs were performed as previously described³. Antibodies used are reported in Supplementary Table 4. Images were acquired on a Zeiss Axio Imager with a Zeiss AxioCam MRn camera and using the Axiovision Rel. 4.6 Software.

On E14.5 hearts, standard histological procedures were used⁷. Antibodies used are reported in Supplementary Table 4. Images were acquired on a AxioZoom.V16 microscope (Zeiss) and the thickness of the cardiomyocyte layer was measured with the Fiji software. Phenotypic analysis of *Zic3* mutant and WT hearts at E14.5 was performed with a careful stage matching between controls and KO embryos (based on the shape of the limbs).

Mouse lines

Mesp1-Cre mice were previously obtained from Y. Saga⁸. Mice colonies were maintained in certified animal facilities in accordance with European guidelines (7h to 19h light cycle, 20-25°C and 55% +/-15 humidity). The experiments were approved by the local ethical committee

(CEBEA) under protocols #591N (CB) and Apafis #13031 (FL) and a national agreement (#B1301308) (FL). Novel *Zic3* KO mouse lines were generated by injecting two crRNAs targeting sequences flanking the DNA-binding domain of *Zic3*, along with tracrRNA and recombinant Cas9 protein, into zygotes (IDT). Offspring were screened for genomic aberrations within the *Zic3* gene. Two founders were selected to conduct further experiments; one containing a large deletion and the other a large insertion within the *Zic3* gene, both leading to disruptions of the open reading frame (ORF) upstream of its DNA-binding domain encoding sequence.

Phenotypic analysis of *Zic3* KO embryos

Embryos collected at E14.5 were fixed in 4% paraformaldehyde and washed in PBS. Images of the heart and embryo were acquired on a AxioZoom V16 microscope (Zeiss). The areas of the RV and LV were measured with the Fiji software and a ratio was then calculated.

smRNA-FISH experiments

smRNA-FISH was performed according to the protocol of the RNAscope Multiplex Fluorescent v2 Assay (ACD-bio. 323110). In brief, embryos were fixed for 26-30h in 4% paraformaldehyde at 4°C and then dehydrated in methanol. For smRNA-FISH on sections at E6.5-E7.5, the decidua was embedded in paraffin after fixation, dehydrated in methanol and incubated for 16h in butanol at 4°C. For smRNA-FISH on sections of E9.5 chimera, the embryos were embedded in histogel (Eprelia HG-4000-012) prior to paraffin embedding. Tissue sections were cut at 7 to 10 µm. Whole-mount smRNA-FISH was performed as previously described⁹. Probes are reported in Supplementary Table 5. To develop probes, we have used Opal dyes from Akoya Bioscience (Opal-520, Opal-570 and Opal-650, from 1:100 to 1:200). Embryos or sections were imaged using an AxioZoom.V16 microscope (Zeiss) or an

LSM800 confocal microscope (Zeiss). When analysing litters from *Mesp1-Cre* or *Zic3* KO lines, embryos were genotyped by PCR after imaging.

Image analyses after smRNA-FISH experiments

To analyse the expression of *Mesp1* expression in EBs, images were analysed with the Fiji software (v2.1). We used guidelines from ACD-bio on how to quantify RNAscope Fluorescent Assay Results. First, the *Average Background Intensity (ABI)* was calculated based on $\frac{\Sigma \text{integrate intensity of selected background regions}}{\Sigma \text{area of selected background regions}}$. To measure signal intensity (SI), cells where *Mesp1* expression was detected were selected (ROI). $SI = \text{Total intensity of ROI} - ABI \times \text{Total Area}$. To quantify the percentage of cells expressing *Mesp1*, we also selected pixels with $SI > ABI$. We used the DAPI channel to measure the surface area (SA) of the EBs. Similarly, in another channel, we estimated the SA of regions expressing *Mesp1* transcripts. We used the ratio between the SA of *Mesp1* + pixels over the SA of the nuclei staining (DAPI+) to estimate the percentage of cells within the EBs that express *Mesp1*.

To estimate the percentage of chimerism in *Zic2/3* dKO cells in WT embryos, images from RNAscope experiments were analysed. We estimated the *ABI* for each channel as described above. We then selected pixels with $SI > ABI$. All positive pixels were selected, and their SA measured. We used the DAPI channel to measure the SA of the embryo in a selected section. Similarly, in another channel, we estimated the SA of regions expressing *tdTomato*. We used the ratio between the SA of *tdTomato*+ pixels over the SA of the nuclei staining (DAPI+) to estimate the percentage of chimerism in the embryo. To estimate the percentage of chimerism in cardiomyocytes, we selected the region with *Tnnt2*+ cells. To estimate the percentage of chimerism in non-cardiomyocytes heart cells, we selected the cardiac region and subtracted the area with *Tnnt2* expression.

Chimeric embryo generation with *Zic2/3* KO TdTomato+ cells

TdTomato-expressing mouse PSCs were generated as previously described¹⁰, and maintained in Lif/2i conditions¹¹. *Zic3* knockout was performed using exactly the same strategy with same targeting guide RNAs used for knocking out *Zic3* in *Mesp1-3HA* inducible PSCs (Supplementary Table 1). Then, *Zic2* knockout was performed on this *Zic3* KO TdTomato-expressing PSC line. Three *Zic2/Zic3* KO clones were selected, and their genotype was confirmed using PCR and sequencing. These PSCs were injected into WT blastocysts in 6 rounds, chimeras were harvested at E7.5, E9.5 and E13.5. No tdTomato⁺ cells were found at E13.5. tdTomato⁺ cells were analysed at E9.5 in three embryos, which were sectioned for RNAscope experiments.

Bioinformatic analysis of bulk RNA-seq

Raw sequenced reads were trimmed using Trimmomatic (v0.39) for quality of bases and eliminating sequencing adapters¹². Cleaned FastQ files were aligned to the mouse genome using STAR (v2.7.3)¹³. Read counts were generated for all refSeq genes using HTSeq-count (v0.11.3)¹⁴. Counts were normalized for all samples as reads per million of mapped reads for each gene. Only genes that had an expression > 1 read per million for both duplicates of one or more conditions were kept for further analysis.

Differentially expressed genes were defined with DESeq2 (v1.34) using a cut-off adjusted p-value of 0.05 and a minimum of 1.5 fold-change expression between both conditions¹⁵. Dox and no dox conditions were compared separately at 12 hours and 24 hours, then these two lists of differentially expressed genes were pooled together to define their kinetics of expression. Genes with a standard deviation higher than 50% of the mean expression were further eliminated. Genes were first classified as up- or downregulated by using a threshold of 1.5 fold-change ($\frac{\text{mean dox}}{\text{mean no dox}} > 1.5$ or $< \frac{1}{1.5}$ respectively). To classify upregulated genes into early, constant and late activated, we calculated the slope of increased expression from 0 to 12h (a)

and from 12 to 24h (b) in dox and no dox conditions. The resulting slopes $a = a_{\text{dox}} - a_{\text{no dox}}$ and $b = b_{\text{dox}} - b_{\text{no dox}}$ were calculated to take into account endogenous patterns of gene expression. Genes were defined as early if $a/b > 3$, late if $b/a > 3$, and constant when a/b was intermediate. If the two slopes went in opposite direction, the slope with highest absolute value was preferred to the other, and the gene was defined either as early ($a > 0$ and $b < 0$) or late ($a < 0$ and $b > 0$). Basic plots were constructed using the R package ggplot2¹⁶. When comparing Mesp1-inducible WT cells to KO cells for Zic2, Zic3 or both, we used DESeq2 to call differentially expressed genes between cell types and added a cut-off fold-change value of 2¹⁵. For comparing Flk1⁻/Pdgfra⁻ with Flk1⁺/Pdgfra⁺ cells, DESeq2 was used in addition to a 1.5-fold change threshold to call differentially expressed genes. The same was used for RNA-seq samples collected in 2i, taking into account only genes expressed at least 1 read per million.

Analysis of microarray data in Mesp1-expressing cells *in vivo*

Genes up-regulated in GFP⁺ (Mesp1-positive) expressing cells *in vivo* were defined by microarray as genes presenting at least 2-fold change stronger signal in E6.75 or E7.25 GFP⁺ versus GFP⁻. We then classified these genes as early, constant and late depending on the ratio of expression between E6.75 and E7.25 GFP⁺ cells. Genes with at least 1.5-fold higher expression at E6.75 were classified as early, whereas genes with at least 1.5-fold higher expression at E7.25 as late. All intermediate genes were classified as constant.

Analysis of Mesp1 ChIP-seq and H3K27Ac ChIP-seq

Raw sequenced reads were trimmed using Trimmomatic for quality of bases and eliminating sequencing adapters¹². Single-end (replicate 1) or paired-end (replicate 2) sequencing reads were uniquely aligned to the mouse genome using Bowtie2 (v2.4.2)¹⁷. Picard tools were used to remove PCR duplicates (Broad Institute), samtools (v1.2.10) to remove mitochondrial reads and low-quality alignments¹⁸. Peaks were called using MACS2 (v2.4.2) with a threshold of

$p=10^{-10}$ and using the input sequencing as background¹⁹. Mesp1 ChIP-seq peaks from 12 and 24 hours were compared between both replicates, and only the intersection of both were kept for further analysis. Then, peaks from both time points were merged in a single file for annotation, motif analysis and read counting. Reads in all peaks were counted using HTseq-count¹⁴. Mesp1 ChIP-seq peaks were classified as early binding if $\frac{n_{\text{reads}}(12\text{h})}{n_{\text{reads}}(24\text{h})} > 2$, late if this ratio < 0.5 , and constant for all intermediate values. To annotate peaks to genes, we used GREAT (v4.0.4)²⁰ with a maximum distance of 500 kb to the TSS. Ngsplot (v2.63) was used for data visualization²¹.

Analysis of H3K4me1, Mesp1 ChIP-seq in 2i and in Zic2/3 double KO cells

FastQ files were cleaned and trimmed using Trimmomatic¹². Paired-end reads were aligned using Bowtie2¹⁷. Picard tools were used to remove PCR duplicates (Broad Institute), samtools to remove mitochondrial reads and low-quality alignments¹⁸. Peaks were called using MACS2 with a threshold p-value of 10^{-10} ¹⁹. Where duplicates available (all the Mesp1 ChIP-seq samples), the intersection peaks of both replicates were kept for further analysis. For Mesp1 ChIP-seq samples, peaks were then compared to those obtained in Mesp1 ChIP-seq during differentiation using BEDtools²².

Analysis of ATAC-seq

FastQ files were cleaned and trimmed using Trimmomatic¹². Paired-end reads were aligned using Bowtie2¹⁷. Picard tools were used to remove PCR duplicates (Broad Institute), samtools to remove mitochondrial reads and low-quality alignments¹⁸. Peaks were called using MACS2 with a threshold p-value of 10^{-10} ¹⁹. Peaks from all experiments from the WT cell line were merged, and reads were counted for each condition in all merged peaks using HTSeq-count¹⁴. Peaks that were up- or downregulated in dox versus no dox were defined with DESeq2, using an adjusted p-value of 0.05 as threshold¹⁵. Peaks were annotated with the same parameters as

above using GREAT²⁰. To define the peaks that were upregulated in dox conditions without being bound by Mesp1, we excluded all Mesp1 ChIP-seq peaks with a p-value cut-off of 0.1 from the file of upregulated peaks.

To define *de novo* versus primed Mesp1-bound enhancers, we performed a second round of peak calling in our ATAC-seq samples at 24 hours dox and 0 hours using a q-value cut-off of 0.05. *De novo* peaks were defined as Mesp1 ChIP-seq peaks not presenting a peak at 0 hours but presenting one at 24 hours dox. Primed peaks encompassed peaks that presented an ATAC-seq peak at 0 hours and undefined Mesp1 peaks, which did not present a peak neither at 0 nor 24 hours dox. Nucleosome eviction after Mesp1 induction was also assessed using HHMRATAC (v1.2.10)²³, a tool for assessing nucleosome positioning in ATAC-seq data. We quantified the overlap between Mesp1 ChIP-seq peaks and nucleosome-bound DNA, as predicted by HHMRATAC (v1.2.10).

For the analysis of ATAC-seq performed in 2i and Zic2/3 dKO cell lines, reads in peaks were counted as above, then up- and downregulated peaks were defined using DESeq2 with a threshold of $p_{adj} < 0.05$ and minimum fold-change = 2. For Flk1⁻/Pdgfra⁻ and Flk1⁺/Pdgfra⁺ samples, DESeq2 was used with a cut-off at $p = 0.05$ and a minimum fold-change average read enrichment of 2.

Footprinting and bHLH motif quantification

ATAC-seq footprints were defined within Mesp1 ChIP-seq peaks using HINT-ATAC (v0.13.1)²⁴ on merged ATAC-seq data at 24h dox. The number of occurrence of each possible bHLH motif was quantified within these footprints and represented as a barplot.

Motif discovery and analysis

Different sets of peaks were analysed for known and *de novo* motif enrichment of TF motifs using Homer (v4.11.1)²⁵. Algorithm parameters were set to find motifs of 6, 8, 10 and 12

nucleotides in a region of 500 bp around the peak centre. Homer was also used to define which peaks within a set of peaks contained a particular motif.

Analysis of Zic2 and Zic3 ChIP-seq

Paired-end sequencing reads were treated as for the ATAC-seq for trimming, filtering and alignment. Peaks were called with a cutoff at $q=0.05$, since these ChIP-seq were generated using endogenous-tagging antibodies. For Zic3 ChIP-seq, replicates were performed and only the peaks present in the intersection of both replicates of the same condition were kept for further analysis. Motif enrichment was performed as above.

Data Availability Statement

NGS Data has been deposited in Gene Expression Omnibus (GEO) and is accessible through GEO Series accession number GSE165107. To review GEO accession GSE165107: Go to <https://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE165107>, Enter token obkpgysqfrcvdot into the box.
