HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Is Vitamin A an antioxidant?

Torsten Bohn, Volker Böhm, Joanna Dulińska-Litewka, Jean-Francois Landrier, Diana Banati, Omer Kucuk, Patrick Borel, Jose A. Canas and Ralph Rühl

Vitamin A is an essential nutrient for humans and higher animals. It occurs in multiple forms in the body. The primary bioactive derivative, all-*trans*-retinoic acid, is the active ligand for three nuclear hormone receptors, the retinoic acid receptors (RARs; RAR α , RAR β and RAR γ), which mediate the large majority of vitamin A's biological effects, including most physiological effects such as cell differentiation, proliferation and apoptosis. These effects are relevant for a large array of pathways enabling the maintenance of a healthy immune response, the cardiovascular system, general development, embryonic development and skin- and epithelial-functions [1-3]. All-*trans*-retinal and 11-*cis*-retinal are vitamin A derivatives involved in the visual cycle where they act in photo-perception [4]. In addition to these active forms, all-*trans*-retinol is the primary homeostatically regulated vitamin A species within the body, and retinyl esters like retinyl palmitate are the storage form that are mainly present in liver and some other organs [5]. In the context of dietary vitamin A intake, plant-derived vitamin A precursors are called provitamin A carotenoids comprising β -carotene, α -carotene and β -cryptoxanthin as three main representatives in our diet. These provitamin A carotenoids [6] serve as food-derived vitamin A precursors converted directly to retinol / retinyl esters in humans or in animals. Various animals serving directly (i.e. meat) or indirectly (i.e. milk / eggs) as human food sources convert further this provitamin A to retinol / retinyl esters, which is then taken up as this directly by humans.

Historically, the term vitamin A comprises retinol / retinyl esters, retinal isomers, and retinoic acid isomers, as well as provitamin A carotenoids and this term vitamin A is often incorrectly associated with antioxidant activity (reviewed in [7, 8]). Recently, two reviews summarised and discussed this antioxidant activity [9, 10] and concluded that vitamin A, in the form of retinal and retinoic acid, as well as retinol and retinyl esters have no direct antioxidant activity in humans [10], contrary to what is often claimed. Another recent review of carotenoids, focusing on provitamin A carotenoids, concluded that on a physiological and nutritional level, provitamin A carotenoids are likely not mediating their biological mechanisms primarily via antioxidant effects [9]. Rather than acting as direct antioxidants, these review articles concluded that the effects of vitamin A in the body involve serving as precursors for ligands for RARs and retinoid X receptors as well as also exert an indirect antioxidant response via NF- κ B and NRF2 signalling pathways [6, 9, 10].

We wish to note here, based on the large amount of data and references discussed in these reviews, which originate independently from both sides of the Atlantic, claiming that vitamin A (as retinol and retinyl esters), and even provitamin A carotenoids, are direct antioxidants *in vivo*, does not reflect the current state of understanding of this nutrient. This claim is particularly problematic when advertising vitamin A (as retinol and retinyl esters) and even provitamin A in food products and in dietary supplements [11]. Unfortunately, overdosing with exclusively vitamin A, mainly in the form of retinol or retinyl ester as food ingredients or dietary supplements that are already taken in sufficient or even high dose in Western countries [12], may result in moderate to even severe toxic effects such as mental / cognitive impairments, pruritus, headache, changes in skin and hair, an imbalanced immune response, muscle and bone pain, hyperlipidemia and potential embryo-toxic effects [12-18]. Consequently, supplementation with vitamin A (as retinol / retinyl ester) may induce moderate to severe toxic side effects instead of the purported antioxidant defence [12].

It is our opinion that vitamin A and even provitamin A carotenoids do mainly not act as a direct antioxidant in the human body and therefore recommend that regulatory bodies and companies fortifying food / selling supplements to reconsider carefully advertising vitamin A with the claim "antioxidant".
