- The GenBank/EMBL/DDBJ accession number for the 16S rRNA sequence of strain 143-21^T is
- OP271781. The complete genome sequence of 143-21^T has been deposited at GenBank/ENA/DDBJ
- under the accession number CP078093.

ABSTRACT

A novel moderately thermophilic heterotrophic bacterium, designated strain 143-21^T, was isolated from a deep-sea hydrothermal chimney sample collected on the Central Indian Ridge at a depth of 2,440 m. Phylogenetic analysis indicated that strain 143-21^T belongs to the genus *Crassaminicella*. It was most closely related to Crassaminicella thermophila SY095^T (96.79 % 16S rRNA gene sequence similarity) and Crassaminicella profunda Ra1766H^T (96.52 %). Genomic analysis showed that strain 143-21^T share 79.79–84.45 % average nucleotide identity (ANI) and 23.50–29.20 % digital DNA-DNA hybridization (dDDH) with the species of the genus Crassaminicella, respectively. Cells were rod-shaped, non-motile, Gram-positive-staining. Terminal endospores were observed in stationaryphase cells when strain 143-21^T was grown on TRM medium. Strain 143-21^T was able to grow at 30-60 °C (optimum 50 °C), pH6.5–8.5 (optimum 7.0), and in NaCl concentration of 1.0–7.0 % (w/v) (optimum 2.0 %, w/v). Strain 143-21^T can utilize fructose, glucose, maltose, mannose, ribose, N-acetyl-D-(+)-glucosamine and casamino acids, as well as amino acids including glutamate, lysine, histidine, and cysteine. The main fermentation products from glucose were acetate (2.07 mM), H₂ and CO₂. It did not reduce elemental sulfur, sulfate, thiosulfate, sulfite, fumarate, nitrate, nitrite and Fe (III). The predominant cellular fatty acids were $C_{14:0}(48.8 \%)$, $C_{16:0}(12.9 \%)$, and summed Feature 3 contained $C_{16:1}$ ω 7c and/or $C_{16:1}$ ω 6c (10.2 %). The major polar lipids were diphosphatidylglycerol, phosphatidylethanolamine, and phosphatidylglycerol, as well as two unidentified phospholipids, and four unidentified aminolipid. No respiratory quinones were detected. Based on the phylogenetic analysis and physiological characteristics, strain 143-21^T is considered to represent a novel species of the genus Crassaminicella, for which the name Crassaminicella indica sp. nov. is proposed. The type strain is strain $143-21^{T}$ (=DSM 114408^{T} = MCCC $1K06400^{T}$).

Deep-sea hydrothermal vent represent a typical chemosynthetic ecosystem, which are fueled by geothermal chemical energy (1, 2). The chemical-rich hydrothermal fluid erupted from the vent and rapidly mixed with surrounding cold seawater, resulting in steep thermal and chemical gradients. Chemoautotrophic microorganisms can exploit these chemical disequilibria to produce energy for carbon fixation and support the vent food chain (3). Vent ecosystem also contains a high fraction of heterotrophic microorganisms, such as *Alkaliphilus pronyensis* (4), *Caminicella sporogenes* (5), *Clostridium tepidiprofundi* (6), *Paramaledivibacter caminithermalis* (7), *Serpentinicella alkaliphila*, and *Wukongibacter baidiensis* (7). Interestingly, microbial communities inhabiting deep-sea hydrothermal vent varies with the chimney from the cradle to the grave, heterotrophic microorganisms would become dominant after the hydrothermal activity has ceased (8). In addition, numerous heterotrophic groups have been isolated from hydrothermal sediments and exhibited hydrolysis activity of hexadecane or polycyclic aromatic hydrocarbons (9). These versatile heterotrophic groups play a vital role in the deep-sea biogeochemical cycles.

Species in the genus *Crassaminicella*, originated in the deep-sea environment, are heterotrophic and was first proposed by R. Lakhal et al (10), which can ferment carbohydrates and organic acids. The genus *Crassaminicella* belongs to the family *Clostridiaceae* of the order *Eubacteriales* of the class *Clostridia* in the phylum *Bacillota*. At the time of writing, this genus includes only two valid published species (https://lpsn.dsmz.de/genus/crassaminicella), *Crassaminicella profunda* Ra1766H^T (10) isolated from the sediment of Guaymas Basin at a depth of 2,002 m, and *Crassaminicella thermophila* SY095^T (11) isolated from the chimney sample of the Southwest Indian Ridge at a depth of 2,730 m. Genome analysis has revealed their diverse metabolic characteristics and adaptive strategies in the deep-sea environment (12, 13). Here, we report the isolation and characterization of a novel species of the genus *Crassaminicella*, strain 143-21^T, originating from a deep-sea hydrothermal

vent in the Center Indian Ridge (CIR). The phenotypic and physiological features of novel species will expand our knowledge about the genus *Crassaminicella*.

77

Isolation and Ecology

- 80 During the TS10-3 cruise of the research vessel 'Tan Suo Yi Hao' in February 2019, the active
- chimney fragments were collected at a depth of 2,440 m from the *Kali* hydrothermal field (25.32°S,
- 82 70.04°E) of CIR, by using the manned submersible 'Shen Hai Yong Shi'. The chimney surface was
- 83 covered by blind shrimps, few sea anemones attached to the rock near the root of the chimney. The
- 84 highest temperature of the hot vent fluid was 373 °C, which measured by a K-type thermocouple
- probe inserted into the vent opening. The chimney fragments were obtained by the robotic arm of
- 86 manned submersible and placed in a closed biobox filled with sterile seawater. Once onboard, the
- 87 fragment was crushed under sterile conditions, and then stored anaerobically at 4 °C until culturing
- attempts.
- 89 The stored chimney debris (about 0.5 g) were transferred into Hungate tubes containing 10 ml of
- anaerobic Thermococcales Rich Medium (TRM) with N₂ as the headspace gas, and then incubated at
- 91 50 °C without shaking. After incubation over one week, the medium becomes cloudy indicating the
- 92 growing of microorganisms. To obtain pure cultures, the enrichment culture was spread anaerobically
- 93 on plates of TRM solidified with agar (2 %, w/v), and grow at 50 °C for one week. One colony was
- 94 picked for repeated plate streaking, the purity of the isolate was confirmed by microscopic
- 95 observations and by repeated sequencing of the 16S rRNA gene. The purified strain was designated
- 96 143-21^T and stored at -80 °C in TRM supplemented with 5 % (v/v) DMSO for long-term
- 97 preservation. The strain 143-21^T can also grow well in the JCM 909 medium composed of NaCl,
- 98 NH₄Cl, KH₂PO₄, K₂HPO₄, L-cysteine-HCl, MgCl₂·6H₂O, NaHCO₃, yeast extract and glucose etc. The
- anaerobic JCM 909 medium was prepared as described by Li et al. (11). Further investigations were
- 100 carried out using JCM 909 medium unless otherwise stated.

101

102

16S RNA phylogeny

- The complete sequence of the 16S rRNA gene (1,527 bp) of strain 143-21^T was retrieved from the
- genomic sequence, and was then compared with available sequences in the NCBI GenBank
- 105 (nucleotide collection nr/nt database). 16S rRNA gene sequence analysis indicated that strain 143-21^T
- belongs to the family *Clostridiaceae* of the phylum *Bacillota*. The closest phylogenetic relative is
- 107 Crassaminicella thermophila SY095^T (96.79 %), and Crassaminicella profunda Ra1766H^T (96.52 %),
- followed by *Inediibacterium massiliense* Mt12^T (94.63 %), *Anaerophilus nitritogenes* MJB2^T
- 109 (94.45 %), Geosporobacter ferrireducens IRF9^T (94.00 %), Marinisporobacter balticus 59.4M^T
- 110 (93.58 %), Wukongibacter baidiensis DY30321^T (92.73 %), Anaerosolibacter carboniphilus IRF19^T
- 111 (92.29 %), Salimesophilobacter vulgaris Zn2^T (91.54 %). All the 16S rRNA gene sequences of the
- closely related strains obtained from the GenBank database were aligned using sina aligner
- 113 (https://www.arb-silva.de/aligner/), phylogenetic analysis was performed by using the software
- MEGA (version 11). A neighbor-joining phylogenetic tree of representative members was constructed
- based on the 16S rRNA gene sequences. Bootstrap analysis was performed with 1000 replications.
- Phylogenetic relationships showed that strain 143-21^T belonged to the genus *Crassaminicella* and
- formed a clade with *C. thermophila* SY095^T and *C. profunda* Ra1766H^T (Fig. 1). The phylogenetic

topology of these *Crassaminicella* species was also confirmed using the minimum-evolution (Fig. S1A) and maximum-likelihood methods (Fig. S1B).

120

121

118

119

Genome Features

- For genomic DNA extraction, strain 143-21^T was grown on the JCM 909 medium at 50 °C. Cells 122 were harvested in late exponential-phase by centrifugation (4500 g, 20 min). Genomic DNA was 123 extracted using a MagAttract DNA Kit (Qiagen, USA) according to the manufacturer's instructions. 124 125 The whole-genome sequencing was carried out by Nextomics Biosciences Co., Ltd. (Wuhan, China) 126 by using the PromethION and MGI-SEQ 2000 systems. More than 2.5 Gb of clean data were generated for the genome assembly. Briefly, strain 143-21^T genome contains a single circular 127 128 chromosome comprising 2,756,133 nucleotides with 31.10 % G+C content. A total of 2,427 proteincoding sequences (CDS), 121 tRNA genes, and 33 rRNA genes including 5S, 16S, and 23S rRNAs 129 each containing 11 gene copies were identified (13). These 16S rRNA gene sequences show 99.94 % 130 131 similarity. The genome sequence of strain 143-21^T was deposited at DDBJ/ENA/GenBank with an accession number of CP078093. To date, three Crassaminicella genomes have been reported. Among 132 them, strain 143-21^T and C. thermophila SY095^T are moderate thermophiles with optimal growth of 133 134 50 °C, while C. profunda Ra1766H^T is mesophilic with optimal growth of 30 °C. Comparative genome analysis showed that the abundance of COG category in strain 143-21^T and C. thermophila 135 SY095^T, such as Nucleotide transport and metabolism (F), Coenzyme transport and metabolism (H), 136 137 Translation, ribosomal structure and biogenesis (J), and Mobilome: prophages, transposons (X), are higher than the C. profunda Ra1766H^T. These differences may reflect the genome characteristics of 138 moderate thermophile, which will help them to survive in the deep-sea hydrothermal vent. 139
 - The phylogenetic tree based on the 120 concatenated bacterial marker proteins was constructed (14), and the topology indicated that strain 143-21^T formed a distinct branch with C. profunda Ra1766H^T and C. thermophila SY095^T (Fig. S2). Average nucleotide identity (ANI) was calculated by online analysis sites EZBioCloud (https://www.ezbiocloud.net/tools/ani) (15). The DNA-DNA hybridization (dDDH) between two genomes was calculated using GGDC 2.0 (http://ggdc.dsmz.de/ggdc.php#) (16). The average amino acid identity (AAI) between strain 143-21^T and its closest phylogenetic relative was determined using MiGA (17). Strain 143-21^T show 84.45 % and 79.79 % ANI value with C. profunda Ra1766H^T and C. thermophila SY095^T respectively (Table S1), which are significantly lower than the proposed threshold values of 95–96 % (18). The dDDH values between the genomes of strain 143-21^T and two reference genomes were significantly lower than 70 % cutoff value previously proposed for species delimitation (19), which are 29.20 % and 23.50 % for C. profunda Ra1766H^T and C. thermophila SY095^T, respectively (Table S1). In addition, the AAI values between strain 143-21^T and the related species (81.50 % and 66.78 % for C. profunda Ra1766H^T and C. thermophila SY095^T, respectively) are also in the range of standard criteria (65 %<AAI < 95 %) for different species of the same genus (20). Taken together, these results confirmed that strain 143-21^T is a distinct species of the genus Crassaminicella.

Physiology and Chemotaxonomy

- Strain 143-21^T was grown on the JCM 909 medium at 50 °C. The morphology of cells from late
- exponential-phase was observed by phase-contrast microscopy (BX53 with a DP80 digital camera;
- Olympus, Tokyo, Japan) and transmission electron microscopy (JEM-1230; JEOL Ltd., Tokyo,

- Japan). Cells were straight rod-shaped, with a length of $7.1 \pm 1.5 \,\mu m$ and a width of $1.1 \pm 0.3 \,\mu m$. The
- rods were non-motile without flagella (Fig. 2). Cells were stained using Gram Stain Kit (Beijing
- Solarbio Science and Technology) and the results showed that cells were Gram-stain-positive.
- 164 Terminal endospores were observed in stationary-phase cells when the strain 143-21^T was grown on
- 165 TRM medium.
- Physiological characterization of strain 143-21^T was carried out in the JCM 909 medium. 8 ml
- anaerobic JCM 909 medium was dispensed into the serum bottle with a volume of 11 ml with N₂ as
- the headspace gas. The prepared medium was inoculated with cells from late exponential-phase and
- the final cell number is approximately 10⁶ cells ml⁻¹. All experiments were carried out anaerobically
- and all conditions were tested in triplicate unless stated otherwise. Growth was monitored by
- measuring optical density at 600 nm as described by Dai et al. (21). Growth rates were calculated as
- described by Li et al. (11) and shown in Fig. S3. The temperature range for growth was determined at
- 20–75 °C with 5 °C intervals. Strain 143-21^T grew over the range from 25 to 60 °C, the optimal
- growth temperature is 50 °C. No growth was observed at 20 °C and 65 °C after 48 h of incubation.
- 175 The pH range for growth was tested at 50 °C from 5.0–9.0 at intervals of 0.5 pH units. The different
- pH values were adjusted at room temperature (about 28 °C) with 5 M HCl or 5 M NaOH. For
- different pH ranges, the JCM 909 medium was modified with following buffers (each at a
- 178 concentration of 10 mM): MES [2-(*N*-morpholino) ethanesulfonic acid] for pH 5.0–6.0; PIPES
- 179 (piperazine-*N*, *N*9-bis-2-ethane sulfonic acid) for pH 6.5–7.0; HEPES [4-(2-hydroxyethyl)-1-
- piperazineethanesulfonic acid] for pH 7.5–8.5; and no buffer for pH 9.0. After autoclave, media with
- various pH values were adjusted to required values with sterilized stock solutions of 5 M HCl or 5 M
- NaOH. The pH growth range for strain 143-21^T was 6.5–8.5, and the optimal pH for growth was pH
- 7.0. No growth was observed at pH 6.0 or pH 9.0. To determine the NaCl tolerance, strain 143-21^T
- was grown at 50 °C and pH 7.0. JCM 909 medium with gradients of 0–8 % NaCl (w/v) concentration
- was prepared at 0.5 % intervals. Strain 143-21^T grew in NaCl concentrations of 1.0–7.0 % (w/v), with
- optimum growth at 2.0 % (w/v).
- For the analysis of the utilization of sole carbon sources, the basal 909 medium was prepared as
- described by Lakhal et al. (10). The tested substrates were added to basal 909 medium with a final
- concentration of 20 mM. Then, the prepared medium with various substrates were filtered through
- 190 sterilized 0.22 µm Millipore filters (Merck Millipore). These media were inoculated with cells from
- late exponential-phase and the final cell number is approximately 10⁶ cells ml⁻¹. The basal 909
- medium and normal JCM 909 medium were also inoculated and set as the negative and positive
- 193 control, respectively. The following substrates were tested: fructose, glucose, maltose, mannose,
- ribose, N-acetyl-D-(+)-glucosamine, cellobiose, galactose, glycerol, lactose, mannitol, raffinose,
- rhamnose, sorbose, sucrose, xylose, tryptone, acetate, butyrate, formate, lactate, pyruvate, succinate,
- ethanolamine, casamino acids, glutamate, lysine, histidine, cysteine, glutamine, methionine, serine,
- alanine, arginine, asparagine, aspartate, glycine, isoleucine, leucine, phenylalanine, proline, tyrosine,
- valine, tryptophan, and threonine. Strain 143-21^T was found to be able to utilize fructose, glucose,
- maltose, mannose, ribose, and N-acetyl-D-(+)-glucosamine. Other single carbon sources were not
- used under the tested condition. Strain 143-21^T was able to utilize casamino acids, glutamate, lysine,
- 201 histidine, and cysteine. Other amino acids including glutamine, methionine, serine, alanine, arginine,
- asparagine, aspartate, glycine, isoleucine, leucine, phenylalanine, proline, tyrosine, valine, tryptophan,
- and threonine were not utilized. The fermentation products of glucose were analyzed as described by
- Li et al. (11). The main products of glucose fermentation were acetate (2.07 mM), H₂ and CO₂. The
- ability of strain 143-21^T to use electron acceptors was tested by adding sulfur (1 %, w/v), sulfate (20
- 206 mM), thiosulfate (20 mM), sulfite (2 mM), fumarate (20 mM), nitrate (10 mM), nitrite (2 mM) and Fe
- 207 (III) (13 mM) to the JCM 909 medium, respectively. None were used as terminal electron acceptors.

- The cellular fatty acid profiles of strain 143-21^T and reference strains were determined. Cells grown
- on JCM 909 medium under optimal conditions were collected in late exponential-phase by
- centrifugation (4500 g, 20 min). The optimal conditions is 50 °C, pH 7.0, NaCl 2.0 % (w/v) for strain
- 211 143-21^T, 50 °C, pH 7.0, NaCl 2.5 % (w/v) for *C. thermophila* SY095^T, and 30 °C, pH 7.0, NaCl 2.5 %
- 212 (w/v) for *C. profunda* Ra1776H^T. Fatty acids were prepared by the Marine Culture Collection of
- 213 China (MCCC) according to the instructions of the Microbial Identification System (MIDI), and were
- 214 then analyzed by gas chromatography (model 6850; Agilent Technologies) and identified by the
- TSBA 6.0 database (22). The primary cellular fatty acids of strain $143-21^{T}$ were $C_{14:0}$ (48.8 %), $C_{16:0}$
- 216 (12.9 %), and summed Feature 3 contained $C_{16:1}$ ω 7c and/or $C_{16:1}$ ω 6c (10.2 %). The dominant fatty
- acid was $C_{14:0}$ (48.8 %), which was same as *C. thermophila* SY095^T ($C_{14:0}$, 60.5 %) and *C. profunda*
- Ra1776H^T ($C_{14:0}$, 44.9 %). However, strain 143-21^T contains higher proportion of $C_{16:0}$ and $C_{18:0}$ than
- 219 C. thermophila SY095^T and C. profunda Ra1776H^T (Table S2). The polar lipids were extracted using
- a chloroform/methanol system and analyzed using one-& two-dimensional TLC. Strain 143-21^T show
- a polar lipid composition of diphosphatidylglycerol (DPG), phosphatidylethanolamine (PE), and
- phosphatidylglycerol (PG), two unidentified phospholipids (PL1, PL2), and four unidentified
- aminolipids (AL1, AL2, AL3, AL4) (Fig. S4). No respiratory quinones were detected which was
- 224 consistent with the results of the reference strain.
- Overall, strain 143-21^T show a close phylogenetic relationship with *C. thermophila* SY095^T and *C.*
- 226 profunda Ra1776H^T from the genus Crassaminicella. However, strain 143-21^T could distinguished
- with them by its optimal growth conditions (Table 1), physiological characterization (Table 1), cell
- 228 morphology, cellular fatty acids composition (Table S2), and genome relatedness. Therefore, we
- suggested that strain $143-21^{T}$ (=DSM 114408^{T} = MCCC $1K06400^{T}$) represents a novel species of the
- 230 genus Crassaminicella, for which the name Crassaminicella indica sp. nov. is proposed.

231 Description of Crassaminicella indica sp. nov.

- 232 Crassaminicella indica (in'di.ca. L. fem. adj. indica, pertaining to the Indian Ocean, where the strain
- was isolated).
- Cells are Gram-stain-positive, strictly anaerobic, non-motile, rod-shaped without flagella, 1.1 ± 0.3
- μ m in width and $7.1 \pm 1.5 \mu$ m in length. Spores occur with terminal swelling in nutritional restriction.
- 236 Cell growth range is as followed: temperature 25–60 °C (optimum 50 °C), pH 6.5–8.5 (optimum 7.0),
- NaCl 1.0–7.0 % (w/v) (optimum 2.0 %, w/v). Able to utilize fructose, glucose, maltose, mannose,
- ribose, *N*-acetyl-D-(+)-glucosamine, casamino acids, glutamate, lysine, histidine, cysteine. Cellobiose,
- 239 galactose, glycerol, lactose, mannitol, raffinose, rhamnose, sorbose, sucrose, xylose, tryptone, acetate,
- butyrate, formate, lactate, pyruvate, succinate, ethanolamine, glutamine, methionine, serine, alanine,
- arginine, asparagine, aspartate, glycine, isoleucine, leucine, phenylalanine, proline, tyrosine, valine,
- 242 tryptophan, and threonine are not utilized. Terminal electron acceptors such as elemental sulfur,
- sulfate, thiosulfate, sulfite, fumarate, nitrate, nitrite, and Fe (III) are not utilized. The major
- fermentation products from glucose are acetate, H₂ and CO₂. The main cellular fatty acids consist of
- $C_{14:0}$ and $C_{16:0}$. The major polar lipids are diphosphatidylglycerol, phosphatidylethanolamine,
- phosphatidylglycerol, two unidentified phospholipids, and four unidentified aminolipid. No
- respiratory quinones are detected.
- The type strain, strain $143-21^{T}$ (=DSM 114408^{T} = MCCC $1K06400^{T}$), was isolated from deep-sea
- 249 hydrothermal vent chimney at a depth of 2,440 m in the Kali hydrothermal field of the Central Indian
- Ridge. The DNA G+C content of the type strain is 31.1 %. The GenBank/EMBL/DDBJ accession
- number for the 16S rRNA sequence of strain 143-21^T is OP271781. The complete genome sequence
- of 143-21^T has been deposited at GenBank/ENA/DDBJ under the accession number CP078093.

FIGURES AND TABLES

Fig. 1. Neighbor-joining phylogenetic tree based on 16S rRNA sequences of strain 143-21^T and its relatives. Bootstrap values above 50 % based on 1,000 replicates are shown at nodes. Filled circles indicate nodes also recovered with minimum evolution and maximum-likelihood methods. The respective GenBank accession numbers are given in parentheses. Bar, 2 nucleotide substitutions per 1,000 nucleotide positions.

Fig. 2. Transmission-electron microscopy image of a cell of strain 143-21^T. Bar: 1 μm.

Table. 1. Differential phenotypic characteristics of strain 143-21^T and its closely related species Strains: 1, *Crassaminicella indica* 143-21^T; 2, *Crassaminicella thermophila* SY095^T; 3,

Crassaminicella profunda Ra1766H^T. +, Positive; –, negative.

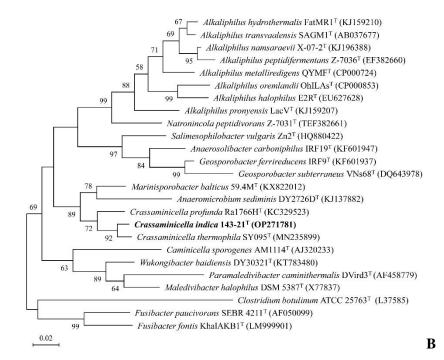

Fig. S1. Minimum evolution (A) and maximum likelihood (B) phylogenetic trees based on 16S rRNA sequences of strain 143-21^T and its closest relatives. Bootstrap values above 50 % based on 1,000 replicates are shown at nodes. The respective GenBank accession numbers are given in parentheses. Bar, 2 nucleotide substitutions per 1,000 nucleotide positions.

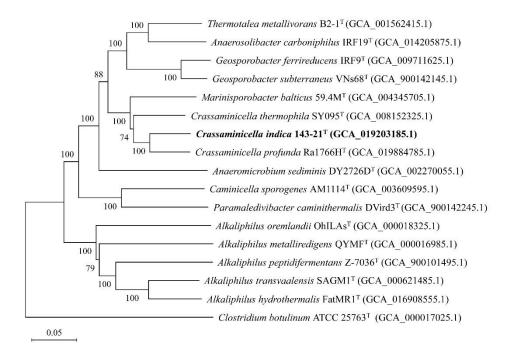

Fig. S2. Neighbor-joining phylogenetic tree of strain 143-21^T and its closest relatives based on the concatenated 120 bacterial marker proteins using the MEGA version 11. The evolutionary distances were computed using the p-distance method and are in the units of the number of amino acid differences per site. The respective GenBank accession numbers are given in parentheses. Bootstrap values above 50 % based on 1,000 replicates are shown at nodes. Bar, number of amino acid differences per site.

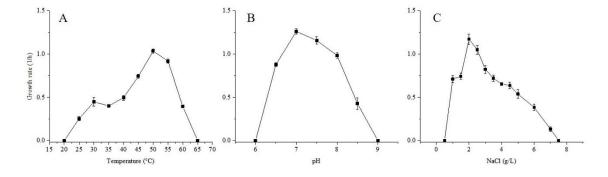

Fig. S3. Effects of temperature (A), pH (B) and NaCl concentration (C) on the growth of strain $143-21^T$. Each value is the mean of three replicates, mean values \pm SD, n=3.

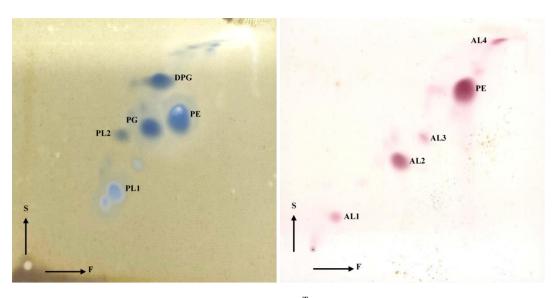

Fig. S4. Polar lipids composition of strain 143-21^T. PL: Phospholipid, PG: Phosphatidylglycerol, DPG: Diphosphatidylglycerol, PE: phosphatidylethanolamine, AL, aminolipid, F-first dimension of TLC; S- second dimension of TLC.

| Strains | DDH (%) | ANI (%) | AAI (%) |
|---|---------|---------|----------------|
| Crassaminicella profunda Ra1766H ^T | 29.20 | 84.85 | 81.50 |
| Crassaminicella thermophila $SY095^T$ | 23.50 | 79.79 | 66.78 |

 Supplementary Table S2. Fatty acid composition of strain 143-21^T and its closely related strains. Strain: 1, 143-21^T; 2, *Crassaminicella thermophila* SY095^T; 3, *Crassaminicella profunda* Ra1766H^T. Values are percentages of total fatty acids. Fatty acids that represented <1 % in all strains were omitted. TR, Traces (<1 %).

| Fatty acid* | Composition (%) in: | | |
|---------------------|---------------------|------|------|
| | 1 | 2 | 3 |
| C _{12:0} | TR | 1.0 | TR |
| $C_{14:0}$ | 48.8 | 60.5 | 44.9 |
| $C_{16:1}\omega 9c$ | 3.4 | 3.4 | 9.0 |
| $C_{16:0}$ | 12.9 | 7.6 | 7.0 |
| $C_{18:0}$ | 3.8 | TR | TR |
| Summed Feature 1 | 2.7 | 5.6 | 1.9 |
| Summed Feature 3 | 10.2 | 14.0 | 29.6 |
| Summed Feature 4 | 9.9 | 3.6 | 3.7 |
| Summed Feature 8 | 3.25 | TR | TR |

^{*}Summed Features are fatty acids that cannot be resolved reliably from another fatty acid using the chromatographic conditions chosen. The MIDI system groups these fatty acids together as one feature with a single percentage of the total. Summed Feature 1 contained iso- $C_{15:1}$ H and/or $C_{13:0}$ 3-OH; Summed Feature 3 contained $C_{16:1}$ ω 7c and/or $C_{16:1}$ ω 6c; Summed Feature 4 contained iso- $C_{17:1}$ I and/or anteiso- $C_{17:1}$ B; Summed Feature 8 contained $C_{18:1}$ ω 7c and/or $C_{18:1}$ ω 6c.
